FRANCIS GALTON

February 16, 1822 – January 17, 1911

by

KARL PEARSON [?]

The death of Francis Galton marks, not only the removal of another link with the leaders of the great scientific movement of the nineteenth century – represented by Darwin, Kelvin, Huxley, Clerk-Maxwell, and Galton in this country – but something far more real to those who have been in touch with him up to the last, namely, the cessation of a source of inspiration and suggestion which did not flag even to the day of his death. The keynote to Francis Galton’s influence over the science of the last fifty years lies in those words: suggestion and inspiration. He belonged to that small group of inquirers, who do not specialise, but by their wide sympathies and general knowledge demonstrate how science is a real unity, based on the application of a common logic and a common method to the observation and treatment of all phenomena. He broke down the barriers, which the specialist is too apt to erect round his particular field, and introduced novel processes and new ideas into many dark corners of our summary of natural phenomena.

The present writer remembers being asked some years ago to provide a list of Francis Galton’s chief scientific achievements for use on a public occasion. It did not seem to him that a list of isolated contributions, such as the establishment of anthropometric laboratories, the introduction of the composite photograph, the transfusion experiments to test pangenesis, the meteorological charts and improved nomenclature, the practical realisation of the possibilities of finger-print identification, the demonstration of the hereditary transmission of the mental characters in man, the law of regression, the idea of stirps, or the foundation of the novel science of Eugenics, fully represented the nature of the man. What is the spirit of the contributions – large and small, almost two hundred in number – which Francis Galton made to the science of the last sixty years? The unity of those contributions lay largely in the idea that exact quantitative methods could be applied, nay, rather must be applied, to many branches of science, which had been held beyond the field of either mathematical or physical treatment. In this manner his inspiration and suggestion tended to give physical and mathematical precision to a large number of outlying sciences, to meteorology, to anthropology, to genetics, and to sociology. In this idea there is nothing novel; many of the world’s great minds have realised the same truth. What did Roger Bacon say towards the middle of the thirteenth century:

“He who knows not mathematics cannot know any other science, and what is more, cannot discover his own ignorance or find its proper remedies.”

How was it echoed again, full two hundred years later, by Leonardo da Vinci?

“Nessuna humana investigazione si po dimandare vera scientia s’essa non passa per le matematiche demonstrationi.” Libro di pittura i, I.

We wait another century and hear Lord Bacon’s aphorism:

“The chief cause of failure in operation (especially after natures have been diligently investigated) is the ill-determination measurement of the forces and actions of bodies. Now the forces and actions of bodies are circumscribed or measured by

---

1His first contribution dates from 1849 and concerns a method of printing telegraphic messages at the receiving station.
distances of space, or by movements of time, or by consideration of quantity, or by predominance of virtue; and unless these four things have been well and carefully weighed, we shall have science, fair perhaps in theory, but in practice inefficient. The four instances which are useful in this point of view I class under one head as Mathematical Instances and Instances of Measurements.

The words actually used by Lord Bacon for his third and fourth instances are “per unionem quanti aut per predominantium virtuti”. They cover very fully the sociological, psychological and genetic phenomena which Francis Galton kept so closely in view.

Another hundred years and again a great thinker echoes the same idea:-

Lastly, coming down to our own age, the great contemporary of Galton, Lord Kelvin, wrote:-

“When you can measure what you are speaking about and express it in numbers, you know something about it, but when you cannot measure it, when you cannot express it in numbers, your knowledge is of a meagre and unsatisfactory kind.”

Clearly, then, Francis Galton was far from originating the idea that exact quantitative methods are applicable far beyond the range of the physical sciences. Wherein lies then his significance for the science of to-day, and, perhaps, more still for the science of the future? Not solely in the fact that he sketched in broad lines the manner in which quantitative methods could be applied to many branches of descriptive science, but that without being a professor or teacher of students, he succeeded in creating a school of enthusiastic disciples who, inspired by him, have carried his work and his suggestions into practice in craniometry, anthropology, sociology, genetics, and medicine.

The elements in Galton’s character and life which made this achievement possible for him are manifold. Heredity, tradition, education, economic independence, all played their parts, and not least among these stands hereditary temperament. No younger man who knew Francis Galton at all intimately failed to be influenced by his marvellous keenness, his wide but wise generosity of suggestion and practical help, and above all, his equable and lovable personality. His manifest pleasure and gratitude for the simplest little thing done for him and duties of others, whether they were his friends or the servants of his own household, produced a reverence which worked its effect, not only on his immediate environment, but upon the men who carried his inspirations and suggestions into practical science.

The exact biological bearing of religious differentiation upon the creation of human types has, perhaps, never been fully studies. The doctrines of George Fox drew together many men and women of a kindred spirit, and the stringent regulations as to outside marriage led not only to a union of similar natures, but, we venture to think, almost created a biological type. Not only did the Society of Friends unite men religiously, but it produced special temperaments genetically. Even to this day it is strange how men whose families have ceased to be Quakers, yet find that their common sympathies and temperaments arise from Quaker descent. Galton owed the evenness of his temper, his placid acceptance of criticism, but his power of steady persistence in his own work.
and his own views, very largely to his Quaker ancestry, to the Galton and Barclay blood. The fact that Galton was never in controversy was, of course, partly due to the novelty of many of his methods and ideas; they were beyond his generation, which left them largely on one side. Even his work on the heredity of the mental and moral characters in man was looked upon as merely academic, and its real bearing on social habits is only now being realised and pressed home.

For one man who had read “Hereditary Genius” (1869), “Human Faculty” (1880), and “Natural Inheritance” (1889), there were ten who had studied “The Origin of Species” or “Man’s Place in Nature.” But the former were the natural sequel to the latter, and Galton realised at once not only, as Darwin and Huxley did, that the new doctrines applied to man, but also that they must eventually be preached as a guide to human conduct in social activities. Looked at from this aspect, his labour to make anthropometry in both its physical and psychical branches an exact science; his discovery that new types of analysis are wanted to replace mathematical function in biological and social studies, and lastly, his advocacy of Eugenics – the science of right breeding and training of man – are seen to be successive steps in a continuous ascent. The positive conception that science exists to serve man, and that its highest function is not merely to supply his material wants, but to show him how to elevate himself by obedience to biological principles, was the crowning conception of his life. But he did not live to see the controversies which will inevitably arise, as the world in general realises that not all its customs, not all its beliefs, not all its supposed morality and charity, are consonant with scientific knowledge.

But if the fact that Galton was never in controversy had partly a basis in the historic evolution of ideas, it was also deeply rooted in his temperament, the temperament of one portion of his stock. He considered criticism, not only as it affected the reputation of his own work, but as it affected his own estimate of the validity of his own work, and he adopted it or passed it by accordingly. Only once do I remember on a public occasion a slight severity in his usually gentle tone. A medical man of distinction, speaking obviously without any knowledge of the literature of the subject, had asserted that the supposition that the children of parents with certain mental and moral peculiarities would reproduce these features, arose from a totally false conception of what the laws of heredity are. The mental and moral aptitudes were for the speaker outside the purview of hereditary investigation. Galton’s reply was very simple: Much of what his critic had said “might have been appropriately urged forty years ago, before accurate measurement of the statistical effects of heredity had been commenced, but it was quite obsolete now.”

That is the extreme limit to which Galton’s Quaker temperament ever, in the presence of the present writer, allowed him to reply, and here it was a question of checking a vague assertion which swept away the best part of a man’s life work unexamined. That this calmness of mental attitude was very largely innate and not due to environment, is well brought out by a quaint little biography of the first eight years of his life, written by his mother (Violett Galton – half-sister of Charles Darwin’s father) when he went to a boarding school in 1830. Would it be safe to suggest that Galton inherited from his Darwin mother his views on family history? Is “The Life History Album” (Macmillan, 1884 and 1903) with its spaces for observations and photographs...
calm temper, his resourcefulness and courage, are sufficiently indicated by a mother who was closely observant, but who could have no knowledge of the future distinction of her youngest child. A further fundamental factor of Galton’s mental outfit was his extraordinary mechanical ingenuity. This may also have been a Darwin heritage, for it has been shown by other members of the stock. At the same time his paternal grandfather, Samuel John Galton, was not only a statistician, but a man of mechanical tastes and a friend of Boulton and Watt, and the same form of ability was markedly evidenced in another grandson, Sir Douglas Galton.

Francis Galton had the mechanical ingenuity which makes a great engineer or experimentalist; his suggestions were always of the simplest kind, and he used the simplest constructions and the simplest materials. Most of his friends will remember his delight in some almost primitive solution of a mechanical difficulty, that possibly they had themselves pondered over and brought to him in despair. Nothing worries the secretary of a scientific society of the editor of a journal more than the vagaries of an author who provides diagrams wholly unsuited to the page-size of their publications; Galton would be ready with a photographic method of modifying the linear scales in different ratios in two directions. Nothing is more trying at lecture or theatre than the tall person or hat; Galton had his “hyperscope” – a simple tube with two reflecting mirrors at 45° by which he saw over or round them, and he would use it in a crowd when he wished to see what was going on beyond it. Or he would carry a wooden brick in as parcel with a long string attached to it; slowly lowering it in a crowd, he would stand on his block of vantage, and raise it again by its string afterwards without attracting observation. Elsewhere it has been said that, if one wanted to put a saddle on a camel’s back without chafing it, to manage the women of a treacherous African tribe, to measure a snail’s shell, or to work a theodolite in the midst of London traffic, Galton would tell you how it might be done.

Beyond mechanical ingenuity he had great wealth of illustration; what he could possibly represent to the eye, he would do, for he had a firm belief that graphic representation is more impressive than mere numbers. Within a fortnight almost of his death, seated outdoors in a shelter, he was discussing with the present writer as eagerly and keenly as he would have done twenty years ago, the best method of graphically representing and comparing typical racial crania.

Through the last years of his life, apart from his eugenic work, he was very busy in trying to deduce quantitative measures of general likeness; evidences of this were given in his letters on portraiture to this Journal, and in his attempts to make a graduated scale of “blurrers,” which like a photometric wedge would equalise divergence until differentiation of the two compared portraits became impossible. Photographs of members of the same family – “similar and similarly blurred,” as the mathematicians of the child, a linear descendant of this biography with silhouette illustration

3This was of much value to him in his later travels. When five years old his mother took him into a field where the servants were trying to catch some geese. Francis immediately ran among them and seizing the old gander by the neck brought him to his mother muttering at the same time to himself the lines from “Chevy Chase”:

“Thou art the most courteous knight,
That ever I did see - -

4Many of the contrivances devised for his first Anthropometric Laboratory are still in current use.
have it – “blurred” more readily than those of strangers in blood. These things amount, not to complete fulfilments, but to suggestions and inspirations. But Francis Galton realised among the earliest that a comparison of the individual organs and characters of local races needs supplementing by a comparison in some manner of two “index” numbers, which by their deviation shall measure the similarity or diversity of these races, each as a unit complex of many individual characters.

Judged from the modern specialist standard, Galton was, perhaps, not a “mathematician,” but he had enough mathematics for most of the purposes of scientific observation, and he knew how to enlist mathematical aid when he required it. Few of those who have really studied his work or come in contact with his singularly clear and logical mind, would have wished his education other than it was. The training in observation provided by hospital clerking under a good clinical teacher, could never have been replaced with profit by years spent over symbolic analysis; the man who would patiently watch the workman in a foreign country plying his chisel or trowel in order to learn differentiation of method in craftsmanship, and then take a lesson himself in handling the tool in the native way, was a born observer, whose talents lay in other fields than the higher abstract analytic. Yet the essential feature of his work was, and his reputation with the future will largely depend on, his extension of analytical methods to the descriptive sciences. Without Gauss the work of Quetelet would have been impossible. Without Quetelet we should perhaps have missed Francis Galton, and from Galton and his school the new methods have spread, and are spreading into the most varied branches of science; in medicine both treatment and diagnosis will be influenced by them, in physiology and psychology their advantages are being admitted, in biology, anthropology, sociology and its latest offspring – eugenics – their importance has been fully recognised. And wherein does the validity of this new treatment consist? It lies very simply in this, that Galton following Quetelet recognised that causation expressible in terms of mathematical function was not the only, or even the chief category, under which men of science can work; that exact methods were applicable to that lower relation or association, which now passes by the name of correlation. To Galton is due the honour of having reached the first simple measure of this relationship, and in the earlier writings of his keen disciple Weldon, we find it called “Galton’s Function,” a name which had to be dropped as the conception became more general and its types differentiated and classified. It ceased to be possible to call after its discoverer a philosophical category wider than that of causation, and embracing causation as a subclass.

The history – at least, the formal history, – of his discovery is very suggestive of the man and his method. He had been studying the size of organs in parents and their offspring, and he formed what is now termed a correlation table; that numerical table he sought to represent graphically, and to his delight and surprise the rough contour lines, which he drew on the table itself, had the appearance of a family of similar and similarly situated ellipses. The line which joined the means of the organs of the offspring was seen to be straight, and to be the locus of the points of contact of a system of parallel tangents to the ellipses. Galton had reached from his graph the fundamental idea of the simplest type of correlation surface – the generalised Gaussian with linear “regression,” and he was not slow to realise its great importance and its wide application to the inter-relationship of contemporaneously varying or associated phenomena. He
summoned mathematical aid, and with the help of Mr. Dickson determined the form of the Gaussian frequency surface. Years afterwards it was discovered that the mathematics of that surface had been worked out by Bravais, in considering the distribution of shots over a target. Nowadays we know that there are frequency surfaces which are not Gaussian. Wherein then does the transcendent importance of Galton’s work lie? Why, in the fact that he was not considering shots at a target, but that he was seeking a key to open a door for exact quantitative methods into the whole range of vital phenomena.

From Bravais’ mathematical treatment of the Gaussian surface nothing followed, until Galton independently rediscovered it with no idea of shots in his mind, but with the idea of investigating problems in genetics, in evolution, and in sociology.

His work first pointed out to us how the whole field of nature lay open to exact numerical treatment, if we dropped the category of causation and adopted that of correlation. Not from Bravais’ mathematics, but from the suggestion and inspiration of Galton’s contour lines on his table of observations, has sprung the whole body of modern statistical theory. The problem of evolution, and the study of heredity, were for Galton actuarial problems. Needless to say, he did not place on one side the study of individuals, he was ever in sympathy with individual observation and experiment. But, as the late Prof. Weldon expressed it in a sentence which had Galton’s hearty assent, “the actuarial method must be an essential part of the equipment of any man who would make and understand such experiments.” It was in this very sense that Galton initiated the Royal Society “Committee for conducting Statistical Inquiries into the Measurable Characteristics of Plants and Animals.” And for a long time he had in mind the eventual foundation and endowment of an experimental station for variation, heredity, and selection, treated by statistical methods. If his gift to posterity be now found to have taken another form from his original idea, the change is not unassociated with his views on the need for adequate statistical treatment, or with the change of purpose and method which led to his withdrawal from the Evolution Committee.

If we turn from the inspiration and suggestion provided by Galton in many varied forms of inquiry to his actual contributions to our knowledge, two will occur to the minds of most readers, not necessarily because they are the most important, but because some statement of them has crept into elementary textbooks and popular works on science. The first of these is the oft-quoted “Law of Regression”; it was not originally a theoretical deduction but deduced by Galton from his own measurements and observations on individuals. It amounts to the statement that if in a stable population, – i.e. one in which no selection is taking place, and which is mating at random – a group of all the parents be selected which have a character of a given intensity, then the

5“The conclusions . . . depend on ideas that must first be well comprehended, and which are now novel to the large majority of readers and unfamiliar to all. But those who care to brace themselves for a sustained effort, need not feel much regret that the road to be travelled over is indirect and does not admit of being mapped beforehand in a way they can clearly understand. It is full of interest of its own. It familiarizes us with the measurement of variability and with curious laws of chance that apply to a vast diversity of social subjects. This part of the inquiry may be said to run along a road on a high level, that affords wide views in unexpected directions, and from which easy descents may be made to totally different goals to those we have now to reach. I have a great subject to write upon, sacrificing accuracy and thoroughness” – (Francis Galton, “Natural Inheritance,” 1889, p. 2). It is those “easy descents” to “totally different goals” which have proved very arduous, not because they were not obvious and easy so soon as the “high level road” had been made, but because they turned out to lead into strictly preserved but largely untitled “strays.”
average of the same character in their offspring will be nearer to the mean of the whole population than the parental value. As Galton stated this statistical result, it has been over and over again verified by mass-investigations. But it has been singularly often misinterpreted by commentators. One group of them extended it into a general law that all populations tend to regress to mediocrity, if we suspend natural selection; they quite overlooked Galton’s statement that the population was stable. No such general regression to mediocrity was involved in Galton’s law of regression; it was a statistical law of distribution of offspring resulting from the stability of the population. Another group of critics selected certain special parents, overlooking Galton’s word “all,” and endeavoured to show that the law did not apply to their offspring, and must therefore be erroneous. The fact is that the very law itself, when applied to the offspring of somatically selected ancestry and not to all parents of the class, shows the cessation of regression, and it is upon this very cessation of regression for selected sub-classes that the general stability of the Galtonian population depends.

The second contribution to the theory of heredity with which Galton’s name has been generally associated is that termed the “Ancestral Law of Heredity.” The conception Galton had in mind was the following one: in a population mating at random and stable in character, what would be the average relation of each class of individuals in the new generation to each grade of their ancestry? Naturally, he measured the relation by aid of the steepness of his regression lines. The degree of resemblance of to successive grades of the ancestry was found to diminish in a geometrical progression. The exact numbers found by Galton from his data (1/3, 1/9, 1/27, &c.) have not been verified by further observation. But the fundamental features of his method, the idea of applying multiple regression and the diminution of the degree of resemblance in a geometric series, have been found correct. Indeed, we now realise that almost any determinental theory – including that of Mendel – leads directly to Galton’s Law of Ancestral Heredity as stated above. No direct test of adequate character has yet been made on Galton’s Law, as it is commonly cited – a form which he originally stated himself with great hesitation (“Natural Inheritance,” p. 136), and which does not appear wholly in accord with other parts of his observational or theoretical treatment. Strange as it may seem, no one has yet worked out the relationship corresponding to the usually stated form of Galton’s Law for a simple Mendelian population breeding at random; the theoretical investigation of it is beset with many analytical difficulties and not a few logical pitfalls. All the criticisms of this law have turned on results deduced from selected gametic ancestors.

It has been asserted with some plausibility that Galton’s deductions would cease to be of any value if we could discover the physiological causes of heredity. To this, we think, answer may be made that Nature does not work like the breeder by testing gametic qualities. She proceeds by selecting with stringency certain grades of somatic qualities, and the intensity of quality, not the gametic value of the individual is her index to survival. Without some degree of correlation between somatic character and gametic value, the Darwinian theory must collapse. This point Francis Galton had ever in mind, and his views on heredity, and his treatment of the subject, always turned on

---

6Certain investigations have been made, but in every case they will be found not to fulfil the conditions as to average relations, which Galton laid down. Galton’s own material for “Basset Hounds” is really inadmissible, for there is scarcely any doubt about the fictitious character of many of the putative sires.
the effect of somatic selection of the ancestry in modifying the somatic characters of
the offspring. Hence the establishment of a definite theory of physiological heredity
would at once have to be followed by a theoretical deduction from that theory of the
degree of resemblance between somatic characters in ancestry and offspring in a pop-
ulation living in natural conditions. The questions of fertility and death-rate in such a
population are actuarial studies. No physiological inquiry as to heredity can supersede
these studies, but such an inquiry may well confirm, or it may modify, the laws originally
stated by Francis Galton for populations mating at random. So far as it is possible
to judge at present, current physiological theories of heredity tend rather to confirm
than refute Galton’s conclusion.

Of the work in the last decade in Galton’s life, it is possibly too early yet to speak
with any decisive judgement. Darwin, writing to Wallace in 1857, uses the following
words:

“You as me whether I shall discuss ‘man.’ I think I shall avoid the subject as so
surrounded with prejudices, though I fully admit it is the highest and most interesting
problem for the naturalist.”

Darwin’s later writings testify that he did not avoid the subject, but probably the ex-
istence of the prejudices to which he refers prevented him from accentuating the direct
practical bearing of the doctrine of evolution on human conduct. The result of this at-
titude of the earlier evolutionists was that their strength was opposed to one wing only
of the army of intellectual inertia. Their critics were theologians and metaphysicians;
there was no question raised of the bearing of evolution on social habit. Evolution ap-
peared merely as a problem of man’s intellectual attitude towards the universe, it was a
philosophical belief, not a practical code of conduct. Francis Galton’s Huxley lecture
of 1901 “On the possible Improvement of the Human Breed under existing conditions
of Law and Sentiment,” slender as it seemed at the time, was really the clarion call
which told us that the time was ripe for the recognition that the doctrines of evolution
and heredity were more than intellectual belief, they were destined to control the future
and determine the relative efficiencies of nations. Others may have thought, some may
have said, the same thing before8; but to Francis Galton belongs the credit of having
said it at the psychological moment, and said it with the emphasis that made many earn-
est men and women understand its gravity. Later, in his paper of 19049, “Eugenics: its

---

2For example, Sir W. Lawrence wrote in 1819:- “The hereditary transmission of physical and moral qualities, so well understood and familiarly acted on in the domestic animals, is equally true of man. A superior breed of human beings could only be produced by selections and exclusions similar to those so successfully employed in breeding our more valuable animals. Yet, in the human species, where the object is of such consequence, the principle is almost entirely overlooked. Hence all the native deformities of mind and body, which spring up so plentifully in our artificial mode of life, are handed down to posterity and tend by their multiplication and extension to degrade the race. Consequently the mass of the population in our large cities will not bear a comparison with that of savage nations, in which, if imperfect or deformed individuals should survive the hardships of their first rearing, they are prevented by the kind of aversion they inspire from propagating their deformities.” What finer text for the eugenist? But Lawrence spoke to a nation still flushed with Waterloo, while Galton, eighty-five years later, appealed to its grandchildren still smarting from South African defeats, and dimly conscious that all was not well with either its physical or mental vigour.

3[Footnote added in this reprint] Nature 70 (1904), 82 and Sociological Papers 1 (1905), 45-50 and 78-79.
Definitions, Scope, and Aims,” Galton more closely defined the lines of development he had in view for the new science:-

“Persistence in setting forth the national importance of eugenics. There are three stages to be passed through: firstly, it must be made familiar as an academic question, until its exact importance has been understood and accepted as a fact; secondly, it must be recognised as a subject the practical development of which deserves serious consideration; and thirdly, it must be introduced into the national conscience, like a new religion. It has, indeed, strong claims to become an orthodox religious tenet of the future, for eugenics cooperate with the workings of Nature by securing that humanity shall be represented by the fittest races. What Nature does blindly, slowly, and ruthlessly, man may do providently, quickly and kindly. As it lies within his power, so it becomes his duty to work in that direction; just as it is his duty to succour neighbours who suffer misfortune. The improvement of our stock seems to me one of the highest objects that we can reasonably attempt. We are ignorant of the ultimate destinies of humanity, but feel perfectly sure that it is as noble a work to raise its level in the sense already explained, as it would be disgraceful to abase it. I see no impossibility in eugenics becoming a religious dogma among mankind, but its details must first be worked out sedulously in the study. Our zeal leading to hasty action would do harm, by holding out expectations of a near golden age, which will certainly be falsified and cause the science to be discredited. The first and main point is to secure the general intellectual acceptance of eugenics as a hopeful and most important study. Then let its principles work into the heart of the nation, who will gradually give practical effect to them in ways that we may not wholly foresee.”

We have cited the whole paragraph, for it is essentially typical of the man, and some word of his message to the nation may fitly appear here. Conspicuously moderate in tone, the study at each point placed before the market-place, it was indeed a wonderful appeal for a man more than eighty-two years of age to make from the public platform. It signified that the time was ripe for the labours of the biologist, the medical man, and the sociologist to grasp what evolution and heredity mean for man, to make out of their science an art, and work thereby for the future of their nation. Nor has that appeal miscarried; its effect may be traced even among the din of controversy and the clash of diverse interests in almost every recent book, or discussion of heredity or evolution. Those of us, who initially doubted the wisdom of propagandism beyond the academic field, have lived to see a very wide public impression made, not only in this country, but notably in Germany. If that movement remains within the lines Galton assigned to it – “no over-zeal leading to hasty action” which will “cause the science to be discredited” – then we may firmly believe that to the future Galton’s life will appear as a rounded whole – the youth of experience and observation, the manhood of development and discovery of method, the old age of practical application.

His school and disciples have lost a leader, but not before he had lived to put the final touches to his work. Of his generosity and helpfulness, his personal modesty and simplicity of nature, many of those who came in touch with him can bear evidence by remembered talk, by letter, and by act. Someday, perhaps, these things may be put together as a memento of the man whose teaching has just ended, but whose life-work

has only begun to run its course. Rewards came to Francis Galton – medals, honorary
degrees, corresponding memberships of many learned societies – they came unsought,
but not unappreciated. His very modesty made him take an almost childlike joy in these
recognitions of his worth, and then present writer remembers with what pleasure, but
a few weeks ago, Galton showed him his recently received Copley medal. But these
things were not of the essence of his life. Few men have worked so little for reputation
and so much for the mere joy of discovering the truth. His three chief pleasures in life
were first to discover a problem, secondly to solve it by a simple but adequate process,
and thirdly to tell a congenial friend of the problem and its solution. What he cared
chiefly for was the sympathy of men who appreciated his special type of work and
understood its relation to human progress. Had he spoken of himself and his feelings,
which he rarely did, he would, we think, have described his purpose in life much in the
words of Huxley:

“To promote the increase of natural knowledge, and to further the application of
scientific methods of investigation to all the problems of life to the best of my ability,
in the conviction which has grown with my growth and strengthened with my strength,
that there is no alleviation for the sufferings of mankind except veracity of thought and
action, and the resolute facing of the world as it is when the garment of make-belief,
by which pious hands have hidden its uglier features, is stripped off.”

But in the fulfilment of his purpose Francis Galton was an optimist. He believed
that man can not only physically control his environment, but with fuller biological
knowledge his future development. Not on this or that contribution to the records of
science, but on the justification of this belief, will depend his fame in the roll of ages.
There are some of us who believe that among the great names cited at the commence-
ment of this paper, Galton’s will not be the last for he has given an inspiration which
will grow to full fruition. Our country has been the land of dominant scientific ideas
rather than of massive contributions to the records of science – gravitation, the sur-
vival of the fitter, the electromagnetic theory – may we yet add – the biological control
of human development? If so, the name of Francis Galton will be closely associated
with the coping stone of the edifice, which had its foundations first securely laid by his
half-cousin, Charles Darwin.
