R2OpenBUGS:
A Package for Running OpenBUGS from R

Abstract
The R2OpenBUGS package provides convenient functions to call OpenBUGS from R. It automatically writes the data and scripts in a format readable by OpenBUGS for processing in batch mode, which is possible since version 1.4. After the OpenBUGS process has finished, it is possible either to read the resulting data into R by the package itself—which gives a compact graphical summary of inference and convergence diagnostics—or to use the facilities of the coda package for further analyses of the output. Examples are given to demonstrate the usage of this package.

Keywords: R, OpenBUGS, interface, MCMC.

1. Introduction
The usage of Markov chain Monte Carlo (MCMC) methods became very popular within the last decade. OpenBUGS (Bayesian inference Using Gibbs Sampling, Spiegelhalter, Thomas, Best, and Lunn 2003) is a popular software for analyzing complex statistical models using MCMC methods. This software uses Gibbs sampling (Geman and Geman 1984; Gelfand and Smith 1990; Casella and George 1992) and the Metropolis algorithm (Metropolis, Rosenbluth, Rosenbluth, Teller, and Teller 1953) to generate a Markov chain by sampling from full conditional distributions. The OpenBUGS software is available for free at http://www.OpenBUGS.info. An introduction to MCMC methods is given in Gilks, Richardson, and Spiegelhalter (1996).

Using OpenBUGS, the user must specify the model to run, and to load data and initial values for a specified number of Markov chains. Then it is possible to run the Markov chain(s) and to save the results for the parameters the user is interested in. Summary statistics of these data, convergence diagnostics, kernel estimates etc. are available as well. Nevertheless, some users of this software might be interested in saving the output and reading it into R (R Development Core Team 2004) for further analyses. OpenBUGS comes with the ability to run the software in batch mode using scripts.

The R2OpenBUGS package makes use of this feature and provides the tools to call OpenBUGS directly after data manipulation in R. Furthermore, it is possible to work with the results after importing them back into R again, for example to create posterior predictive simulations or, more generally, graphical displays of data and posterior simulations (Gelman 2004). Embedding in R can also be useful for frequently changed data or processing a bunch of data sets, because it is much more convenient to use some R functions (possibly within a loop) rather than using “copy &
paste" to update data in OpenBUGS each time; however difficulties have been encountered in this area because both R and OpenBUGS can lock up RAM in the Windows operating system. R is a “language for data analysis and graphics” and an open source and freely available statistical software package implementing that language, see http://www.R-project.org/. Historically, R is an implementation of the award-winning S language and system (Becker and Chambers 1984; Becker, Chambers, and Wilks 1988; Chambers and Hastie 1992; Chambers 1998). R and R2OpenBUGS are available from CRAN (Comprehensive R Archive Network), i.e., http://CRAN.R-Project.org or one of its mirrors. R2OpenBUGS could be ported to the commercial S implementation S-PLUS. Minor adaptions would be needed since S-PLUS lacks some of R’s functions and capabilities. If an internet connection is available, R2OpenBUGS can be installed by typing install.packages("R2OpenBUGS") at the R command prompt. Do not forget to load the package with library("R2OpenBUGS").

The package coda by Plummer, Best, Cowles, and Vines (2004) is very useful for the analysis of OpenBUGS’ output, the reader might want to install this package as well. The CRAN package boa (Bayesian Output Analysis Program) by Smith (2004) has similar aims. JAGS (Just Another Gibbs Sampler) by Plummer (2003) is a program for analysis of Bayesian hierarchical models using Gibbs sampling that aims for the same functionality as classic BUGS. JAGS is developed to work closely together with R and the coda package.

In this paper, we give two examples, involving educational testing experiments in schools (cf. Section 2.1), and incidence of childhood leukaemia depending on benzene emissions (cf. Section 2.2). Details on the functions of R2OpenBUGS are given in Section 3. These functions automatically write the data and a script in a format readable by OpenBUGS for processing in batch mode, and call OpenBUGS from R. After the OpenBUGS process has finished, it is possible either to read the resulting data into R by the package itself or to use the facilities of the coda package for further analyses of the output. In Section 4, we demonstrate how to apply the functions provided by R2OpenBUGS on the examples’ data, and how to analyze the output both with package coda and with R2OpenBUGS’s methods to plot() and print() the output.

2. Examples

In this Section, we introduce two examples which will be continued in Section 4.

2.1. Schools data

The Scholastic Aptitude Test (SAT) measures the aptitude of high-schoolers in order to help colleges to make admissions decisions. It is divided into two parts, verbal (SAT-V) and mathematical (SAT-M). Our data comes from the SAT-V (Scholastic Aptitude Test-Verbal) on eight different high schools, from an experiment conducted in the late 1970s. SAT-V is a standard multiple choice test administered by the Educational Testing Service. This Service was interested in the effects of coaching programs for each of the selected schools.

The study included coached and uncoached pupils, about sixty in each of the eight different schools; see Rubin (1981). All of them had already taken the PSAT (Preliminary SAT) which results were used as covariates. For each school, the estimated treatment effect and the standard error of the effect estimate are given. These are calculated by an analysis of covariance adjustment appropriate for a completely randomized experiment (Rubin 1981). This example was analyzed using a hierarchical normal model in Rubin (1981) and Gelman, Carlin, Stern, and Rubin (2003, Section 5.5).

2.2. Leukaemia registration data

Spatial data usually arises on different, non-nesting spatial scales. One example is childhood leukaemia registration data analyzed by Best, Cockings, Bennett, Wakefield, and Elliott (2001) using ecologic regression. Data are given for Greater London bounded by the M25 orbital motorway. The data are not available as an example in R2OpenBUGS but we use the example here to illustrate alternative calls to the bugs() function and output analysis using the coda package.
Sibylle Sturtz, Uwe Ligges, Andrew Gelman

The observed number of leukaemia cases among children under 15 years old is given at ward level. Census wards are administrative areas containing approximately 5000 to 10,000 people. Central London is divided into 873 wards. The number of incident cases of leukaemia in children is available from 1985 until 1996 from the Office of National Statistics and the Thames Cancer Registry. A plot of these numbers is given in Figure 1.

Additionally, the number of expected cases (cf. Fig. 2) is calculated on the same resolution using population numbers for different age-sex-strata and the national leukaemia rate for the corresponding strata, for details see Best et al. (2001).

It is assumed that benzene emissions have an effect on the incidence rate of leukaemia. Benzene emission rates are available in tonnes per year from an atmospheric emissions inventory for London (Buckingham, Clewley, Hutchinson, Sadler, and Shah 1997) produced by the London Research Centre. They are provided at 1km $\times$ 1km grid cells, giving 2132 grid cells in total. Their spatial distribution is shown in Figure 3.

For further details on the data see Best et al. (2001).

We model these data by Poisson-Gamma models introduced by Best, Ickstadt, and Wolpert (2000) using OpenBUGS. A linking matrix containing information which grid cell belongs to which ward.
and to which amount is required. This matrix is calculated using R. Unfortunately, OpenBUGS
does not support a list format such as directly produced by R. Therefore, the data must be provided
as a matrix with 2132 rows and 873 columns (or vice versa). Most of the entries of this matrix
are zeroes, but using dump() to export it from R yields in a file size of 14.2 MB. Unfortunately,
opening a file of such size really slows OpenBUGS down, and it was not even possible on some
of our PCs. Importing data written by our R2OpenBUGS package does not make any problems
using the batch mode, probably due to memory management issues in OpenBUGS.

3. Implementation

The implementation of the R2OpenBUGS package is straightforward. The “main” function bugs() is intended to be called by the user. In principle, it is a wrapper for several other functions called therein step by step as follows:

1. bugs.data.inits() writes the data files ‘data.txt’, and ‘inits1.txt’, ‘inits2.txt’, ... into the
   working directory. These files will be used by OpenBUGS during batch processing.

   In particular, input for OpenBUGS must not exceed a certain number of digits. Moreover, it
   needs an E instead of an e in scientific notation. Scientific notation is particularly desirable
   because of the “number of digits” limitation. The default (digits = 5) is to, e.g., reformat
   the number 123456.789 to 1.23457E+05.

2. bugs.script() writes the file ‘script.txt’ that is used by OpenBUGS for batch processing.

3. bugs.run() updates the lengths of the adaptive phases in the WinBUGS registry (using
   a function bugs.update.settings()), calls WinBUGS, and runs it in batch mode with
   ‘script.txt’.

4. bugs.sims() is only called if the argument codaPkg has been set to FALSE (the default).
   Otherwise bugs() returns the filenames of stored data. These can, for example, be imported
   by package coda (see the example in Section 4.2, page 10), which provides functions for
   convergence diagnostics, calculation of Monte Carlo estimates, trace plots, and so forth.

   The function bugs.sims() reads simulations from OpenBUGS into R (not necessarily called
   by bugs() itself), formats them, monitors convergence, performs convergence checks, and
   computes medians and quantiles. It also prepares the output for bugs() itself.
These functions are not intended to be called by the user directly. Arguments are passed from \texttt{bugs()} to the other functions, if appropriate. A shortened help file of \texttt{bugs()} listing all arguments is given in Appendix A; for the full version type \texttt{?bugs} in R after having installed and loaded the package \texttt{R2OpenBUGS} (see Section 1).

As known from OpenBUGS, one must specify the \texttt{data} in form of a list, with list names equal to the names of data in the corresponding OpenBUGS model. Alternatively, it is possible to specify a vector or list of names (of mode \texttt{character}). In that case objects of that names are looked for in the environment in which \texttt{bugs()} has been called (usually that is the user’s Workspace, \texttt{GlobalEnv}). If data have already been written in a file called ‘\texttt{data.txt}’ to the working directory, it is possible to specify \texttt{data = "data.txt"}. One will usually want to supply initial values. This can be done either in the form of a function \texttt{inits()} that creates these values, so that different chains can be automatically initialized at different points (see Section 4.1), or by specifying them directly (see Section 4.2). If \texttt{inits()} is not specified, \texttt{bugs()} just uses the starting values created by OpenBUGS; but in practice OpenBUGS can crash when reasonable initial values are not specified, and so we recommend constructing a simple \texttt{inits()} function to simulate reasonable starting points (Gelman et al. 2003, Section C.2). It is also necessary to specify which parameters should be saved for monitoring by specifying \texttt{parameters.to.save}.

The user might also want to change the defaults for the length of the burn-in (\texttt{n.burnin}, which defaults to half the length of the chain) period for every MCMC run and the number of iterations (\texttt{n.iter}, default value 3) that are used to calculate Monte Carlo estimates. The specification of a thinning parameter (\texttt{n.thin}) is possible as well; this is useful when the number of parameters is large, to keep the saved output to a reasonably-sized R object.

By setting the argument \texttt{debug = TRUE}, OpenBUGS remains open after the run. This way it is possible to find errors in the code or the data structure, or even to work with that software as in a usual run. This feature is not available with Linux execution.

It is possible to run one or more Markov chains. The number of chains (\texttt{n.chains}) must be specified together with the chains’ initial values (\texttt{inits}). If more than one Markov chain is requested and \texttt{codaPkg} is set to \texttt{FALSE}, the convergence diagnostic $\hat{R}$ (Brooks and Gelman 1998) is calculated by \texttt{bugs.sims()} for each of the saved parameters.

Since the communication between OpenBUGS and R is based on files, rather huge files will be saved in the working directory by the \texttt{bugs()} call, either files to be read in by \texttt{bugs()} itself, or by the \texttt{coda} package. The user might want to delete those files after the desired contents has been imported into R, and save those objects, e.g., as compressed R data files.

The function \texttt{bugs()} returns a rather complex object of class \texttt{bugs}, if called with argument \texttt{codaPkg = FALSE}. In order to look at the structure of such an object, type \texttt{str(objectname)}. For convenience, \texttt{R2OpenBUGS} provides methods corresponding to class \texttt{bugs} for the generic functions \texttt{print()} and \texttt{plot()}.

So that user will not be overwhelmed with information; summaries of the output are provided by the \texttt{print()} method. That is, some parameters of the \texttt{bugs()} call are summarized, and mean, standard deviation, several quantiles of the parameters and convergence diagnostics based on Gelman and Rubin (1992) are printed. See the example in Section 4.1, page 7, for a typical output. As with Spiegelhalter, Best, Carlin, and van der Linde (2002), the DIC computed by \texttt{bugs.sims()} is defined as the posterior mean of the deviance plus $p_D$, the estimated effective number of parameters in the posterior distribution. We define $p_D$ as half the posterior variance of the deviance and estimate it as half the average of the within-chain variances of the deviance.$^1$

The \texttt{plot()} for objects of class \texttt{bugs} provides information condensed in some plots conveniently arranged within the same graphics device. For an example, see Figure 4 in Section 4.1. It is

---

$^1$In contrast, Spiegelhalter et al. (2002), and OpenBUGS, define $p_D$ as the posterior mean of the deviance evaluated at the posterior mean of the parameter values. We cannot use that definition because the deviance function is not available to our program, which calls \texttt{OpenBUGS} from the “outside”. Both definitions of $p_D$—ours and that introduced by Spiegelhalter et al. (2002)—can be derived from the asymptotic $\chi^2$ distribution of the deviance relative to its minimum (Gelman et al. 2003, Section 6.7). We make no claim that our measure of $p_D$ is superior to that of Spiegelhalter et al. (2002); we choose this measure purely because it is computationally possible giving what is available to us from the \texttt{OpenBUGS} output.
intended to adapt this function to work with MCMC output in general, even if obtained from software other than OpenBUGS.

4. Examples continued

The Examples introduced in Section 4 are continued in this Section. We apply the functions provided by R2OpenBUGS to the examples’ data and analyze the output.

4.1. Schools data

Schools example data (see Section 2.1) are available with the R2OpenBUGS package:

```r
> data(schools)
> schools
   school estimate sd
 1    A  28.39  14.9
 2    B   7.94  10.2
 3    C  -2.75  16.3
 4    D   6.82  11.0
 5    E  -0.64   9.4
 6    F   0.63  11.4
 7    G  18.01  10.4
 8    H  12.16  17.6
```

For modeling these data, we use a hierarchical model as proposed by Gelman et al. (2003, Section 5.5). We assume a normal distribution for the observed estimate for each school with mean \( \theta \) and inverse-variance \( \tau_y \). The inverse-variance is given as \( 1/\sigma_y^2 \) and its prior distribution is uniform on \((0,1000)\). For the mean \( \theta \), we employ another normal distribution with mean \( \mu_{\theta} \) and inverse-variance \( \tau_{\theta} \). For their prior distributions, see the following OpenBUGS code:

```r
model {
  for (j in 1:J) {
    y[j] ~ dnorm (theta[j], tau.y[j])
    theta[j] ~ dnorm (mu.theta, tau.theta)
    tau.y[j] <- pow(sigma.y[j], -2)
  }
  mu.theta ~ dnorm (0.0, 1.0E-6)
  tau.theta <- pow(sigma.theta, -2)
  sigma.theta ~ dunif (0, 1000)
}
```

This model must be stored in a separate file, e.g. ‘schools.bug’, in an appropriate directory, say `c:/schools/`. In R the user must prepare the data inputs the `bugs()` function needs. This can be a list containing the name of each data vector, e.g.

```r
> J <- nrow(schools)
> y <- schools$estimate
> sigma.y <- schools$sd
> data <- list("J", "y", "sigma.y")
```

---

\(^2\)Emacs Speaks Statistics (ESS) by Rossini, Heiberger, Sparapani, Mächler, and Hornik (2004), a package available with GNU Emacs (Stallmann 1999), recognizes and properly formats Bugs model files that have the .bug extension.
Using these data and the model file, we can run an MCMC simulation to get estimates for $\theta$, $\mu$,$\theta$ and $\sigma$,$\theta$. Before running, the user must decide how many chains to be run ($n$.chain = 3) for how many iterations ($n$.iter = 1000). If the length of burn-in is not specified, $n$.burnin = floor($n$.iter/2) is used, that is, 500 in this example. Additionally, the user must specify initial values for the chains, for example by writing a function. This can be done by

```r
> inits <- function(){
+ list(theta = rnorm(J, 0, 100), mu.theta = rnorm(1, 0, 100),
+ sigma.theta = runif(1, 0, 100))
+ }
```

Now, the user can start the MCMC simulation by typing

```r
> schools.sim <- bugs(data, inits, model.file = "c:/schools/schools.bug",
+ parameters = c("theta", "mu.theta", "sigma.theta"),
+ n.chains = 3, n.iter = 1000)
```

in R. For other available arguments, see Appendix A.

The results in objects `schools.sim` can conveniently be printed by `print(schools.sim)`. The generic function `print()` calls the print method for an object of class `bugs` provided by `R2OpenBUGS`. For this example, you will get something like

```r
> print(schools.sim)
Inference for Bugs model at "c:/schools/schools.bug"
3 chains, each with 1000 iterations (first 500 discarded)
n.sims = 1500 iterations saved
mean sd 2.5% 25% 50% 75% 97.5% Rhat n.eff
theta[1] 11.1 9.1 -3.0 5.0 10.0 16.0 31.8 1.1 39
theta[2] 7.6 6.6 -4.7 3.3 7.8 11.6 21.1 1.1 42
theta[3] 5.7 8.4 -12.5 0.6 6.1 10.8 21.8 1.0 150
theta[4] 7.1 7.0 -6.6 2.7 7.2 11.5 21.0 1.1 42
theta[5] 5.1 6.8 -9.5 0.7 5.2 9.7 18.1 1.0 83
theta[6] 5.7 7.3 -9.7 1.0 6.2 10.2 20.0 1.0 56
theta[7] 10.4 7.3 -2.1 5.3 9.8 15.3 25.5 1.1 27
theta[8] 8.3 8.4 -6.6 2.8 8.1 12.7 26.2 1.0 64
mu.theta 7.6 5.9 -3.0 3.7 8.0 11.0 19.5 1.1 35
sigma.theta 6.7 5.6 0.3 2.8 5.1 9.2 21.2 1.1 46
deviance 60.8 2.5 57.0 59.1 60.2 62.1 66.6 1.0 170
pD = 3 and DIC = 63.8 (using the rule, pD = var(deviance)/2)
```

For each parameter, n.eff is a crude measure of effective sample size, and Rhat is the potential scale reduction factor (at convergence, Rhat=1). DIC is an estimate of expected predictive error (lower deviance is better).

Additionally, the user can generate a plot of the results by typing `plot(schools.sim)`. The resulting plot is given in Figure 4. In this plot, the left column shows a quick summary of inference and convergence ($\hat{R}$ is close to 1.0 for all parameters, indicating good mixing of the three chains and thus approximate convergence); and the right column shows inferences for each set of parameters. As can be seen in the right column, `R2OpenBUGS` uses the parameter names in OpenBUGS to structure the output into scalar, vector, and arrays of parameters, in addition to storing the parameters as a long vector.

For the interpretation of these results see Gelman et al. (2003, Section 5.5).

### 4.2. Leukaemia registration data

The leukaemia registration data (see Section 2.2) are used to show data modeling and output reading into R using the `coda` package. A simple model for these data looks as follows:
Figure 4: Plot produced by R2OpenBUGS package for the schools example.

```r
model{
  beta.0 ~ dgamma(a.0, tau.0)
  beta.benz ~ dgamma(a.benz, tau.benz)
  a.0 <- 0.575
  tau.0 <- a.0*2
  a.benz <- 0.575
  tau.benz <- a.benz*2
}```
for (i in 1:I)
{
  count[i] ~ dpois(lambda[i])
  lambda[i] <- p[i]*expect[i]
  for (j in 1:J)
  {
    prop[j,i] <- gamma[j,i]*(benz[j] - benzbar)
  }
  p[i] <- beta.0 + beta.benz*sum(prop[,i])
}

Here count denotes the number of observed incidences of childhood leukaemia in ward i. These are assumed to be Poisson distributed with mean lambda depending on the number of expected cases expect in ward i and an area-specific risk rate p. For calculation of this area specific risk rate we use an intercept beta.0 and a term depending on the weighted sum of benzene emissions benz in each grid cell j. The weights are chosen proportional to the amount of area that ward i and grid cell j have in common.

In R we can define all these data and then initialize the model. The data needed for this example are

benzbar: arithmetic mean of all benzene values,
benz: a vector containing benzene emissions of all 2132 grid cells,
expect: expected number of cases of childhood leukaemia in each of the 873 wards,
count: observed number of childhood leukaemia in these wards,
gamma: a 2132 × 873 matrix containing the amount of area each grid cell and each ward have in common,
J: total number of grid cells, i.e. 2132, and
I: total number of ward cells, i.e. 873.

The parameters we want to store are regression coefficients beta.0 and beta.benz as well as p, the area specific relative risk compared to the reference rate. This reference rate was used to calculate the expected number of cases in each ward.

Since we want to use the coda package for reading the data into OpenBUGS, we specify codaPkg = TRUE in the bugs() call:

```r
> data <- list(benzbar = mean(benz), benz = benz, expect = expect,
+   count = count, gamma = gamma, J = J, I = I)
> parameters <- c("beta.0", "beta.benz", "p")
> inits1 <- list(beta.0 = 1, beta.benz = 1)
> inits2 <- list(beta.0 = 0.5, beta.benz = 0.5)
> inits <- list(inits1, inits2)
> model <- bugs(data, inits, parameters, model.file = "c:/model.bug",
+   n.chains = 2, n.iter = 8000, n.burnin = 5000, n.thin = 1,
+   codaPkg = TRUE )
```
Starting with, e.g.,

```r
> library("coda")
> codaobject <- read.bugs(model)
> plot(codaobject)
```

it is now possible to use the `coda` package for output analyses.

**bugs**  
*Run OpenBUGS from R or S-PLUS*

**Description**

The `bugs` function takes data and starting values as input. It automatically writes a OpenBUGS script, calls the model, and saves the simulations for easy access in R or S-PLUS.

**Usage**

```r
bugs(data, inits, parameters.to.save, n.iter, model.file="model.bug",  
n.chains=3, n.burnin=floor(n.iter / 2), n.thin=1,  
debug=FALSE, DIC=TRUE, digits=5, codaPkg=FALSE,  
OpenBUGS.pgm;ifelse(.Platform$OS.type == "windows" | useWINE==TRUE,  
paste("C:/Program Files/OpenBUGS/OpenBUGS",  
version,"/OpenBUGS.exe",sep=""),"OpenBUGS"),  
version='311',  
working.directory=NULL,  
clearWD=FALSE, useWINE=FALSE, WINE=NULL,  
newWINE=TRUE, WINEPATH=NULL, bugs.seed=1, summary.only=FALSE,  
save.history=(.Platform$OS.type == "windows" | useWINE==TRUE),  
over.relax = FALSE)
```

**Arguments**

- **data** either a named list (names corresponding to variable names in the `model.file`) of the data for the OpenBUGS model, or a vector or list of the names of the data objects used by the model. If `data = "data.txt"`, it is assumed that data have already been written to the working directory in a file called `.data.txt`, e.g. by the function `bugs.data`.

- **inits** a list with `n.chains` elements; each element of the list is itself a list of starting values for the OpenBUGS model, or a function creating (possibly random) initial values. Alternatively, if `inits = NULL`, initial values are generated by OpenBUGS.

- **parameters.to.save** character vector of the names of the parameters to save which should be monitored.

- **model.file** file containing the model written in OpenBUGS code. The extension can be either `.bug` or `.txt`. If the extension is `.bug` and `program="winbugs"`, a copy of the file with extension `.txt` will be created in the `bugs()` call and removed afterwards. Note that similarly named `.txt` files will be overwritten.

- **n.chains** number of Markov chains (default: 3)

- **n.iter** number of total iterations per chain (including burn in; default: 2000)

- **n.burnin** length of burn in, i.e. number of iterations to discard at the beginning. Default is `n.iter/2`, that is, discarding the first half of the simulations.

- **n.thin** Thinning rate. Must be a positive integer. The default is `n.thin = 1`. The thinning is implemented in the OpenBUGS update phase, so thinned samples are never stored, and they are not counted in `n.burnin` or `n.iter`. Setting `n.thin=2`, doubles the number of iterations OpenBUGS performs, but does not change `n.iter` or `n.burnin`. Thinning implemented in this manner is not captured in summaries created by packages such as `coda`.  

---

12
bugs

debug
if FALSE (default), OpenBUGS is closed automatically when the script has finished running, otherwise OpenBUGS remains open for further investigation.

DIC
logical; if TRUE (default), compute deviance, pD, and DIC. This is done in OpenBUGS directly using the rule \( pD = Dbar - Dhat \). If there are less iterations than required for the adaptive phase, the rule \( pD = \text{var} (\text{deviance}) / 2 \) is used.

digits
number of significant digits used for OpenBUGS input, see \texttt{formatC}

codaPkg
logical; if FALSE (default) a \texttt{bugs} object is returned, if TRUE file names of OpenBUGS output are returned for easy access by the \texttt{coda} package through function \texttt{read.bugs}. A \texttt{bugs} object can be converted to an \texttt{mcmc.list} object as used by the \texttt{coda} package with the method \texttt{as.mcmc.list} (for which a method is provided by \texttt{R2OpenBUGS}).

OpenBUGS.pgm
For Windows or WINE execution, the full path to the OpenBUGS executable. For linux execution, the full path to the OpenBUGS shell script (not required if OpenBUGS is in the user’s PATH variable). If the global option \texttt{R2OpenBUGS.bugs.directory} is not NULL, it will be used as the default.

version
The version of OpenBUGS to use. \texttt{version} is ignored with linux execution or if \texttt{OpenBUGS.pgm} is specified.

working.directory
sets working directory during execution of this function; OpenBUGS’ in- and output will be stored in this directory; if NULL, the current working directory is chosen.

clearWD
logical; indicating whether the files ‘data.txt’, ‘inits[1:n.chains].txt’, ‘log.odc’, ‘codelnindex.txt’, and ‘coda[1:nchains].txt’ should be removed after OpenBUGS has finished. If set to TRUE, this argument is only respected if \texttt{codaPkg} = FALSE.

useWINE
logical; attempt to use the WINE emulator to run OpenBUGS. Default is FALSE. If WINE is used, the arguments \texttt{OpenBUGS.pgm} and \texttt{working.directory} must be given in form of Linux paths rather than Windows paths (if not NULL).

WINE
character; name of WINE binary file

newWINE
Set this one to TRUE for new versions of WINE.

WINEPATH
Path the WINE, it is tried hard to get the information automatically if not given.

Details

To run:

1. Write a OpenBUGS model in a ASCII file.
2. Go into R / S-PLUS.
3. Prepare the inputs to the \texttt{bugs} function and run it (see Example).
4. A OpenBUGS window will pop up and R / S-PLUS will freeze up. The model will now run in OpenBUGS. It might take awhile. You will see things happening in the Log window within OpenBUGS. When OpenBugs is done, its window will close and R / S-PLUS will work again.
5. If an error message appears, re-run with \texttt{debug} = TRUE.

Value

If \texttt{codaPkg} = TRUE the returned values are the names of coda output files written by OpenBUGS containing the Markov Chain Monte Carlo output in the CODA format. This is useful for direct access with \texttt{read.bugs}.

If \texttt{codaPkg} = FALSE, the following values are returned:

\begin{itemize}
\item \texttt{n.chains} see Section ‘Arguments’
\item \texttt{n.iter} see Section ‘Arguments’
\item \texttt{n.burnin} see Section ‘Arguments’
\item \texttt{n.thin} see Section ‘Arguments’
\item \texttt{n.keep} number of iterations kept per chain (equal to \((n.iter-n.burnin) / n.thin\))
\end{itemize}
n.sims number of posterior simulations (equal to n.chains * n.keep)
sims.array 3-way array of simulation output, with dimensions n.keep, n.chains, and length of combined parameter vector
sims.list list of simulated parameters:
for each scalar parameter, a vector of length n.sims
for each vector parameter, a 2-way array of simulations,
for each matrix parameter, a 3-way array of simulations, etc. (for convenience, the n.keep * n.chains simulations in sims.matrix and sims.list (but NOT sims.array have been randomly permuted)
sims.matrix matrix of simulation output, with n.chains * n.keep rows and one column for each element of each saved parameter (for convenience, the n.keep * n.chains simulations in sims.matrix and sims.list (but NOT sims.array have been randomly permuted)
summary summary statistics and convergence information for each element of each saved parameter.
mean a list of the estimated parameter means
sd a list of the estimated parameter standard deviations
median a list of the estimated parameter medians
root.short names of argument parameters.to.save and “deviance”
long.short indexes; programming stuff
dimension.short dimension of indexes.short
indexes.short indexes of root.short
last.values list of simulations from the most recent iteration; they can be used as starting points if you wish to run OpenBUGS for further iterations
pD an estimate of the effective number of parameters, for calculations see the section “Arguments”.
DIC mean(deviance) + pD

Examples

# An example model file is given in:
model.file <- system.file(package = "R2OpenBUGS", "model", "schools.txt")
# Let's take a look:
file.show(model.file)
# Some example data (see ?schools for details):
data(schools)
schools

J <- nrow(schools)
y <- schools$estimate
sigma.y <- schools$sd
data <- list("J", "y", "sigma.y")
inits <- function(){
  list(theta = rnorm(J, 0, 100), mu.theta = rnorm(1, 0, 100),
       sigma.theta = runif(1, 0, 100))
}

## or alternatively something like:
## inits <- list(
##   list(theta = rnorm(J, 0, 90), mu.theta = rnorm(1, 0, 90),
##        sigma.theta = runif(1, 0, 90)),
##   list(theta = rnorm(J, 0, 100), mu.theta = rnorm(1, 0, 100),
##        sigma.theta = runif(1, 0, 100))
##   list(theta = rnorm(J, 0, 110), mu.theta = rnorm(1, 0, 110),
##        sigma.theta = runif(1, 0, 110)))

parameters <- c("theta", "mu.theta", "sigma.theta")

## Not run:
## You may need to edit "bugs.directory",
## also you need write access in the working directory:
schools.sim <- bugs(data, inits, parameters, model.file,
                     n.chains = 3, n.iter = 5000)
print(schools.sim)
plot(schools.sim)
## End(Not run)
