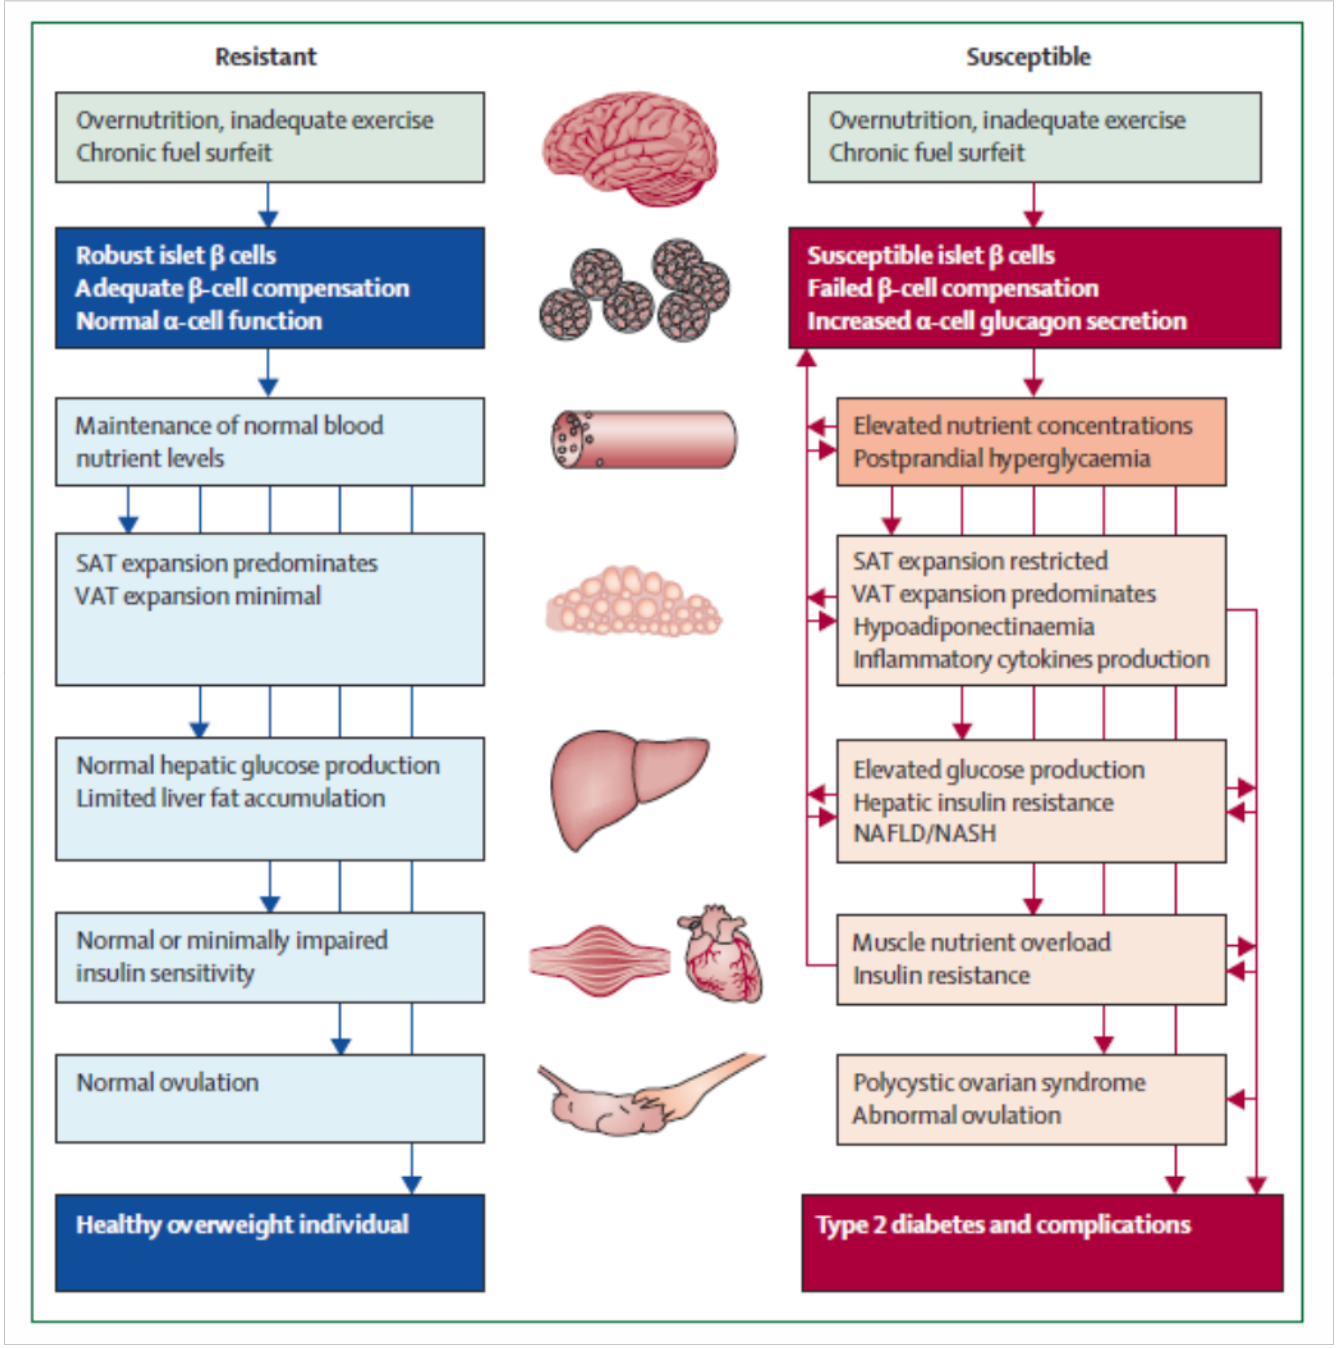
What's New in Type 2?

Peter Hammond
Consultant Physician
Harrogate District Hospital

Therapy considerations in T2DM

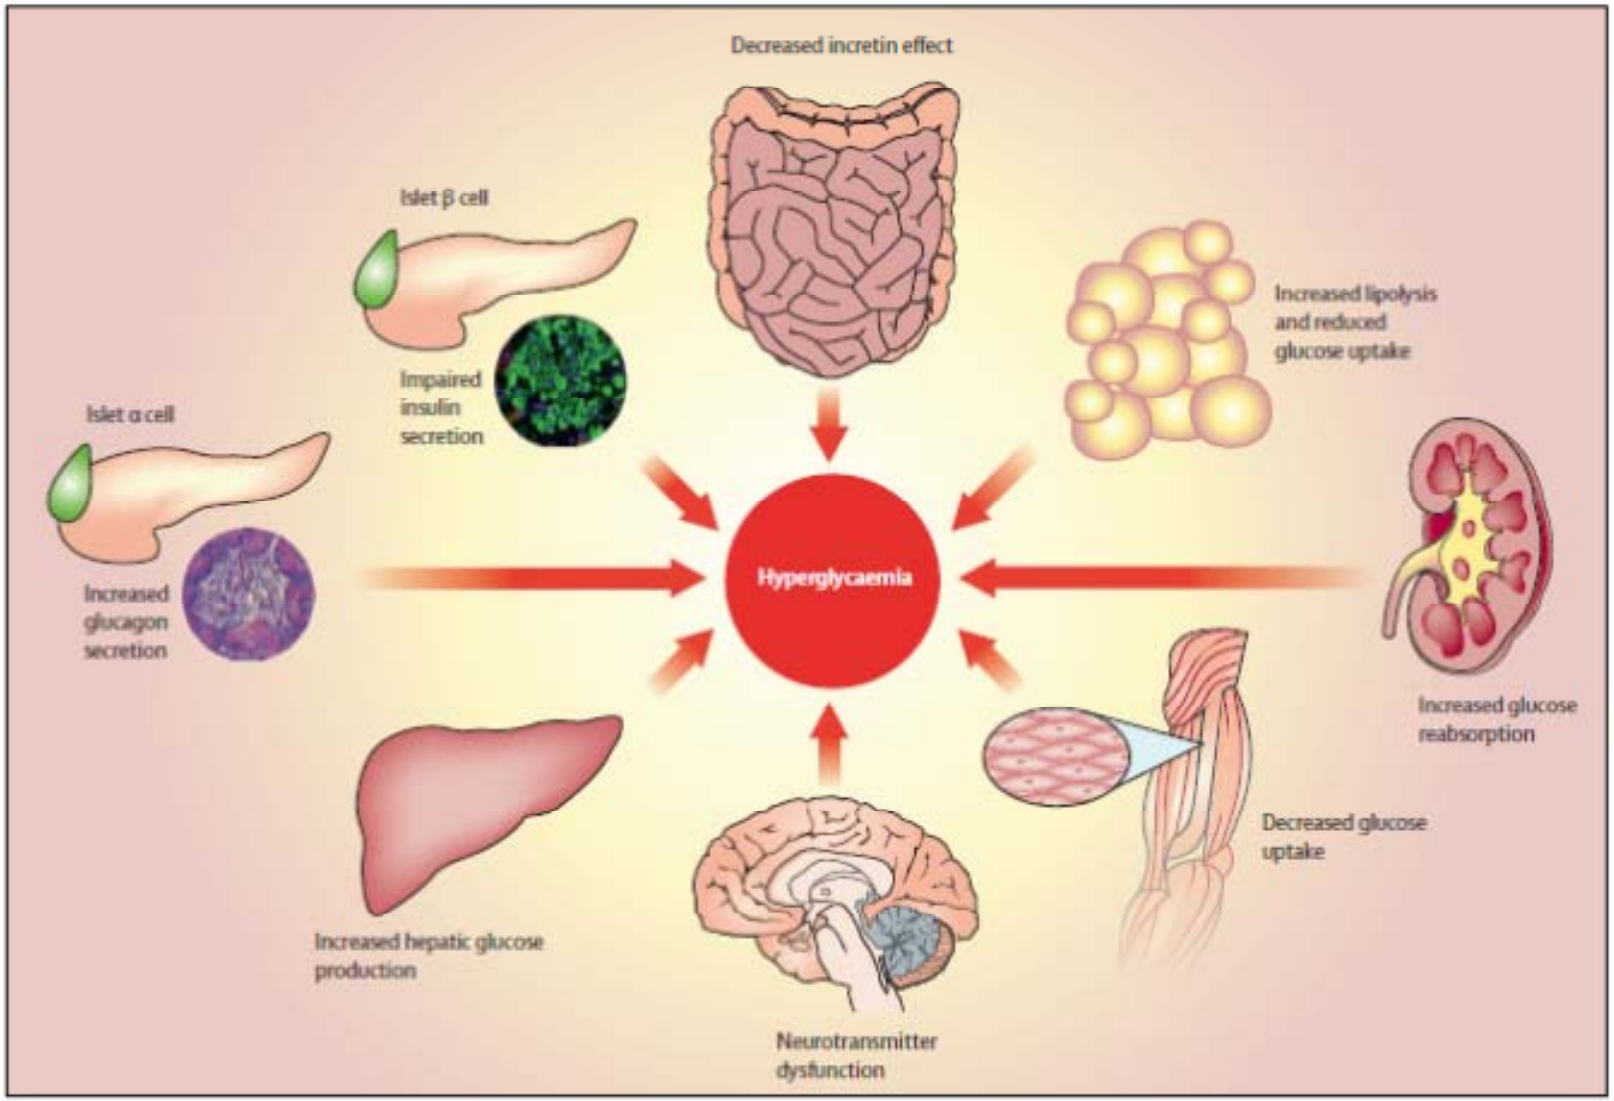
- Thiazoledinediones
- DPP IV inhibitors
- GLP 1 agonists
- Insulin
  - Type
  - Delivery
- Horizon scanning



Nolan CJ et al. *Lancet* 2011;378:169-181

Harrogate and District NHS Foundation Trust

Therapeutic targets



Tahrani A et al. *Lancet* 2011;378:182-197

Panel 2: Desired characteristics of glycaemic control therapies in type 2 diabetes

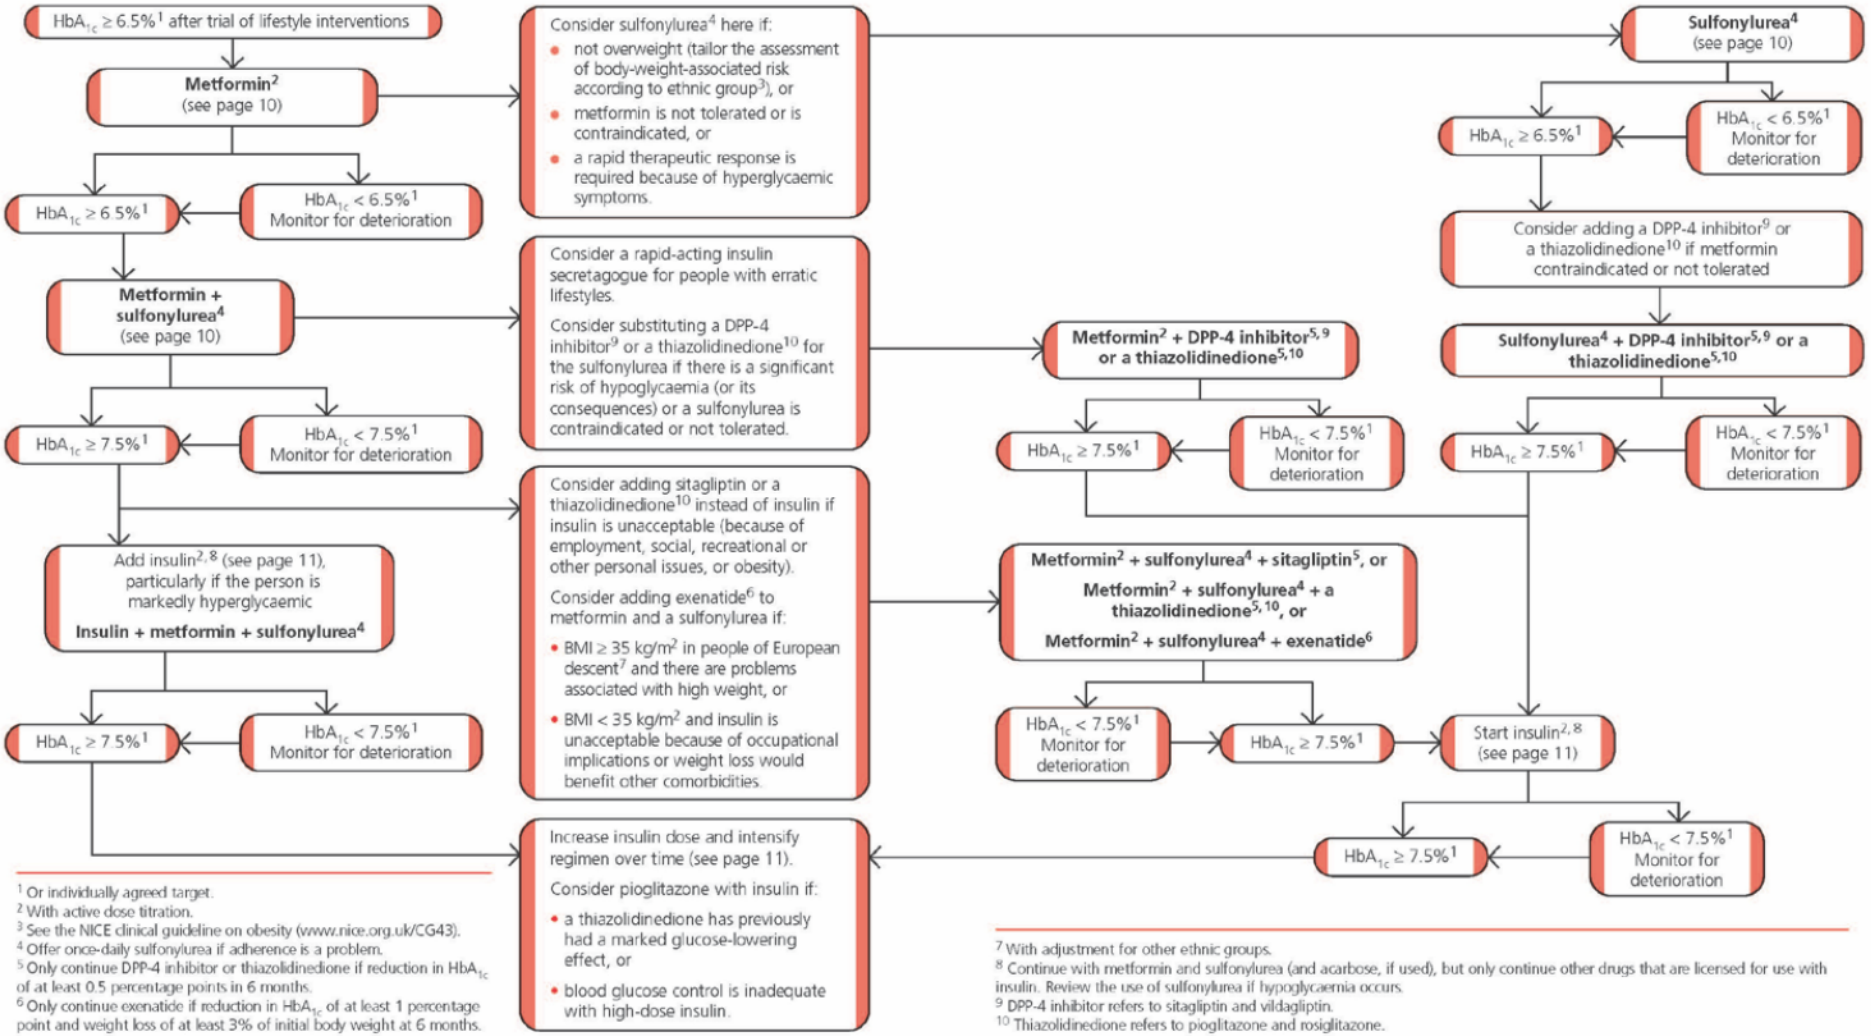
The therapy, in addition to achieving target HbA_{1c}, should:

- Be disease modifying (ie, reverse one or more of the underlying pathophysiological processes)
  - (i) Reduce chronic fuel surfeit
  - (ii) Protect islet β-cells from progressive failure
  - (iii) Prevent adipose tissue dysfunction, including abnormal fat distribution and inflammation
  - (iv) Restore normal islet α-cell function and incretin physiology
  - (v) Restore normal regulation of hepatic glucose production
  - (vi) Enhance skeletal muscle mitochondrial function/oxidative metabolism
  - (vii) Enhance energy expenditure and thermogenesis
- Sustain good metabolic control with low therapy-associated unwanted effects
- Enhance quality of life of patients
- Reduce diabetes microvascular and macrovascular complications
- Reduce diabetes-related mortality (includes cardiovascular disease-related), and all-cause mortality

HbA_{1c}=glycated haemoglobin A_{1c}.

Nolan CJ et al. *Lancet* 2011;378:169-181

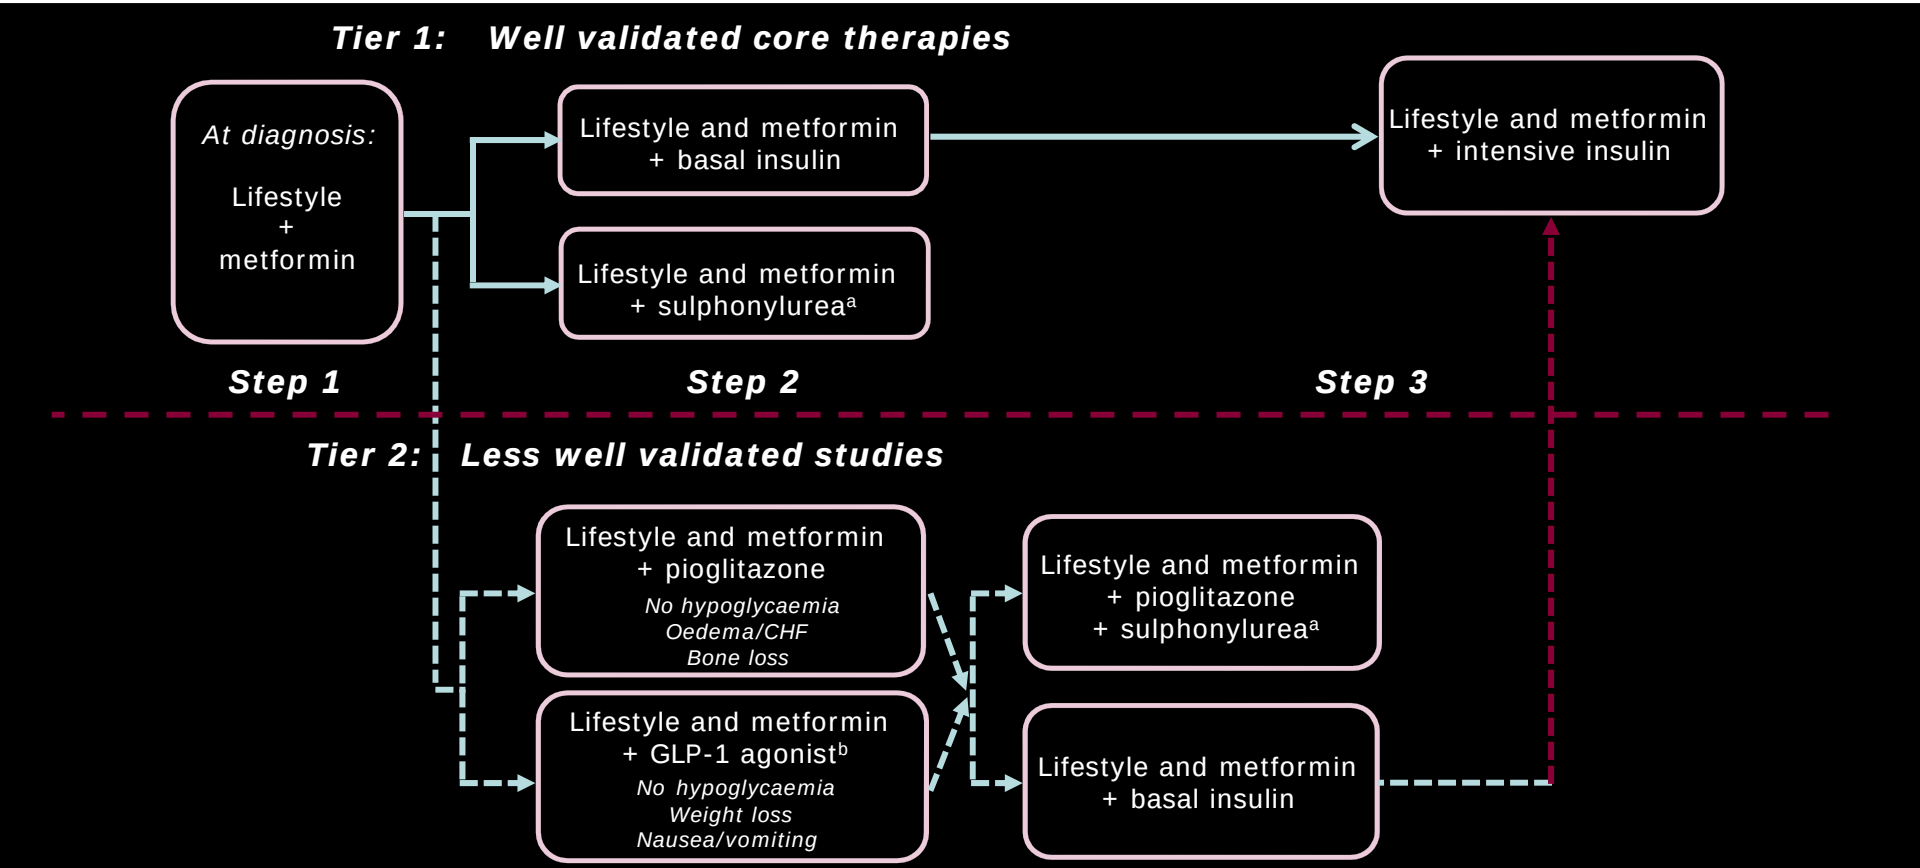
Blood-glucose-lowering therapy



[1] Or individually agreed target.
[2] With active dose titration.
[3] See the NICE clinical guideline on obesity (www.nice.org.uk/CG43).
[4] Offer once-daily sulfonylurea if adherence is a problem.
[5] Only continue DPP-4 inhibitor or thiazolidinedione if reduction in HbA_{1c} of at least 0.5 percentage points in 6 months.
[6] Only continue exenatide if reduction in HbA_{1c} of at least 1 percentage point and weight loss of at least 3% of initial body weight at 6 months.
[7] With adjustment for other ethnic groups.
[8] Continue with metformin and sulfonylurea (and acarbose, if used), but only continue other drugs that are licensed for use with insulin. Review the use of sulfonylurea if hypoglycaemia occurs.
[9] DPP-4 inhibitor refers to sitagliptin and vildagliptin.
[10] Thiazolidinedione refers to pioglitazone and rosiglitazone.

ADA and EASD algorithm

- *Reinforce lifestyle interventions at every visit and check HbA_{1C} every 3 months until HbA_{1C} is <7% and then at least every 6 months. The interventions should be changed if HbA_{1C} is ≥7%.*

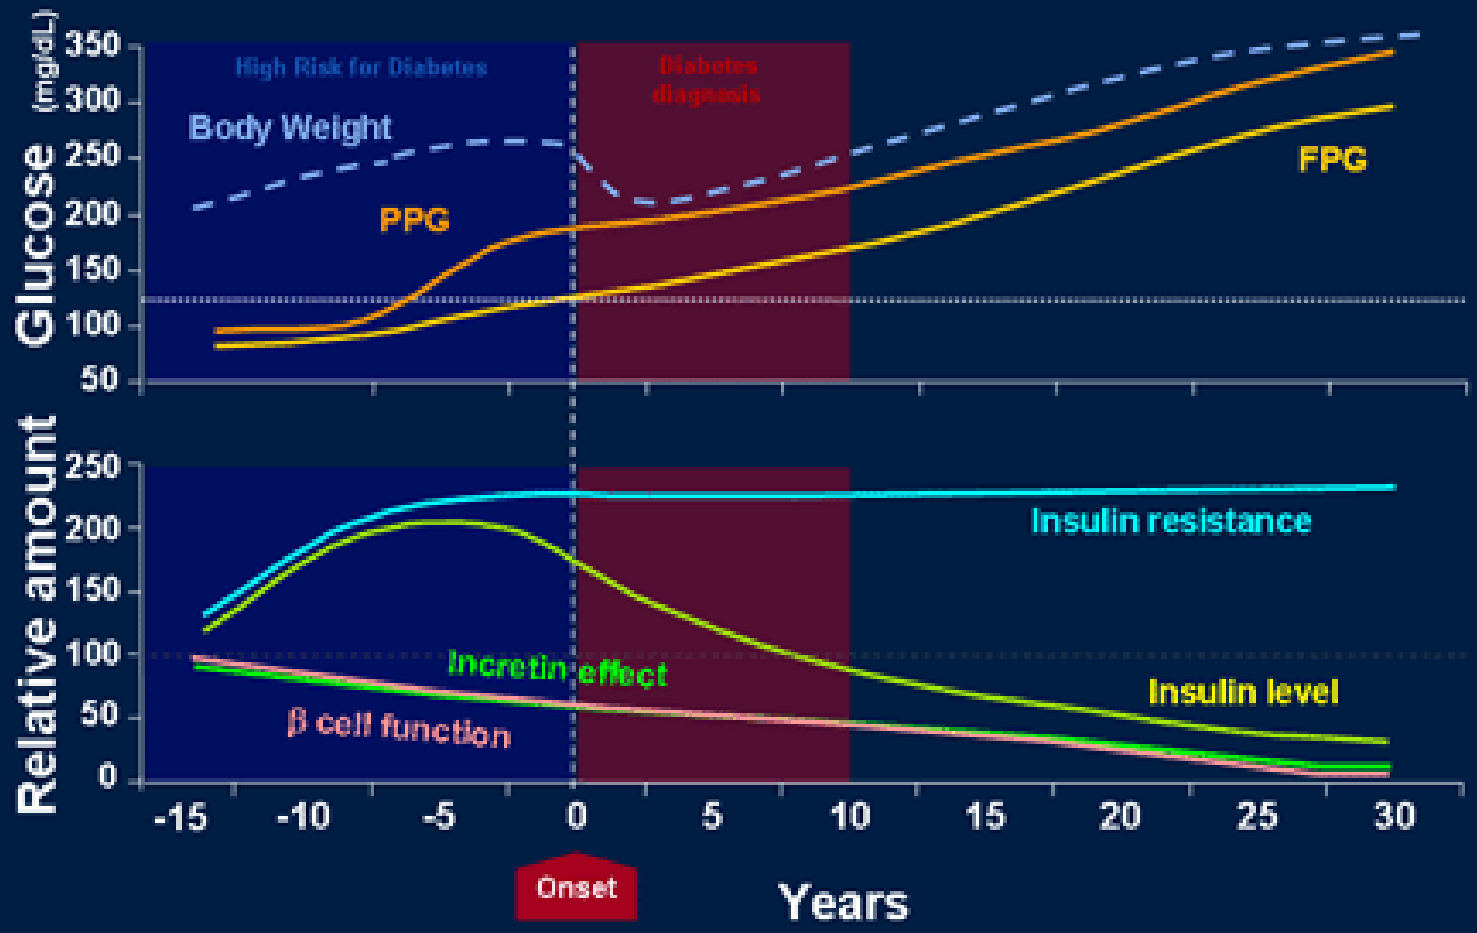


[a]*Sulfonylureas other than glybenclamide (glyburide) or chlorpropamide.*

[b]*Insufficient clinical use to be confident regarding safety.*

Nathan *et al. Diabetes Care* 2008;31:1–11

Natural History of Type 2 Diabetes



Legacy Effect of Earlier Glucose Control

After median 8.5 years post-trial follow-up

Aggregate Endpoint		1997	2007
Any diabetes related endpoint	*RRR:*	12%	9%
	P:	0.029	0.040
Microvascular disease	*RRR:*	25%	24%
	P:	0.0099	0.001
Myocardial infarction	*RRR:*	16%	15%
	P:	0.052	0.014
All-cause mortality	*RRR:*	6%	13%
	P:	0.44	0.007

RRR = Relative Risk Reduction, P = Log Rank

UKPDS 80. N Engl J Med 2008 359

There is no place for pioglitazone in the management of type 2 diabetes

Pioglitazone – pros and cons

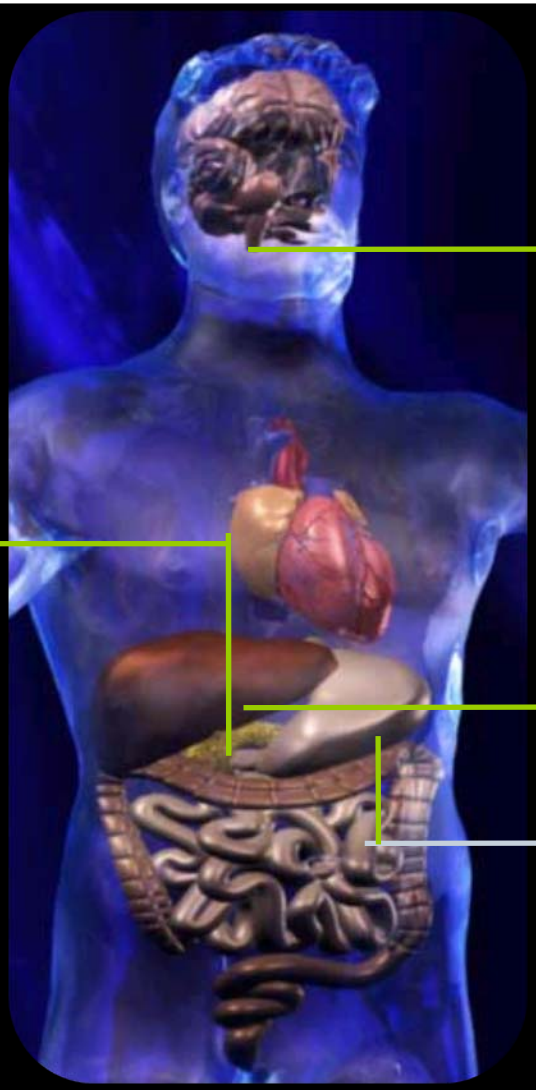
- Bladder cancer: RR 1.12-1.33
  - Avoid if active or PH of bladder ca, or if have uninvestigated haematuria
  - Consider risk factors: smoking, age
- Osteoporosis
- PROACTIVE study: 16% RR in all-cause mortality, non-fatal MI and stroke

MHRA Safety Update August 2011

Pioglitazone – case study

- PH, 78 M
- Jan’ 11: wt 90.1 kg, HbA1c 72 mmol/mol (8.7%)
  - Glargine 20 u am, 50 u pm
  - Metformin 850 mg tds
  - Sitagliptin 100 mg od
- Added pioglitazone 30 mg od
  - Glargine dose reduced to 16 u am, 44 u pm
- July ’11: wt 98.1 kg, HbA1c 57.5 mmol/mol (7.4%)
  - Lows during the night

Physiological effects of GLP1



Pancreas

- ↑ Insulin secretion (glucose-dependent) and beta-cell sensitivity
- ↑ Insulin synthesis
- ↓ Glucagon secretion (glucose-dependent)
- ↑ Beta-cell mass*

Brain

- ↓ Energy intake*

Liver

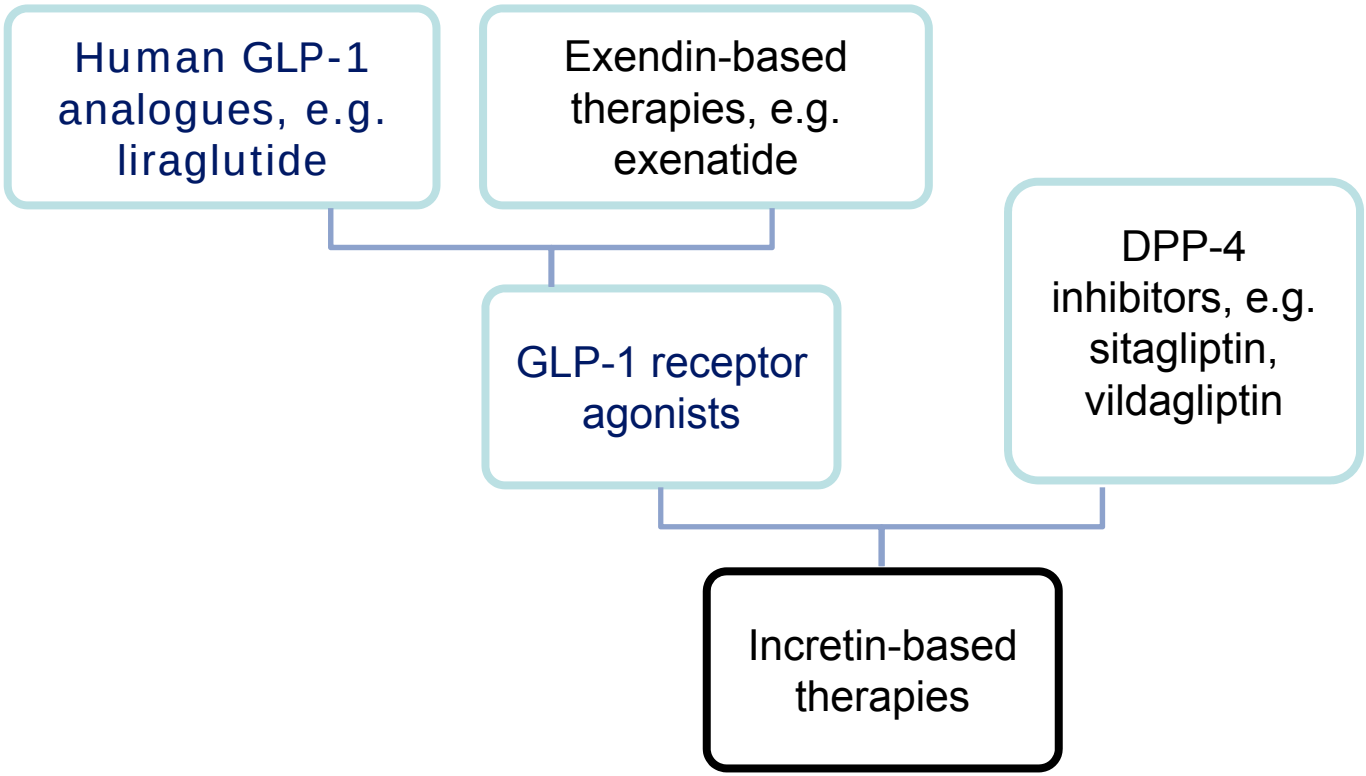
- ↓ Hepatic glucose output

GI tract

- ↓ Decreased motility

*in animal studies

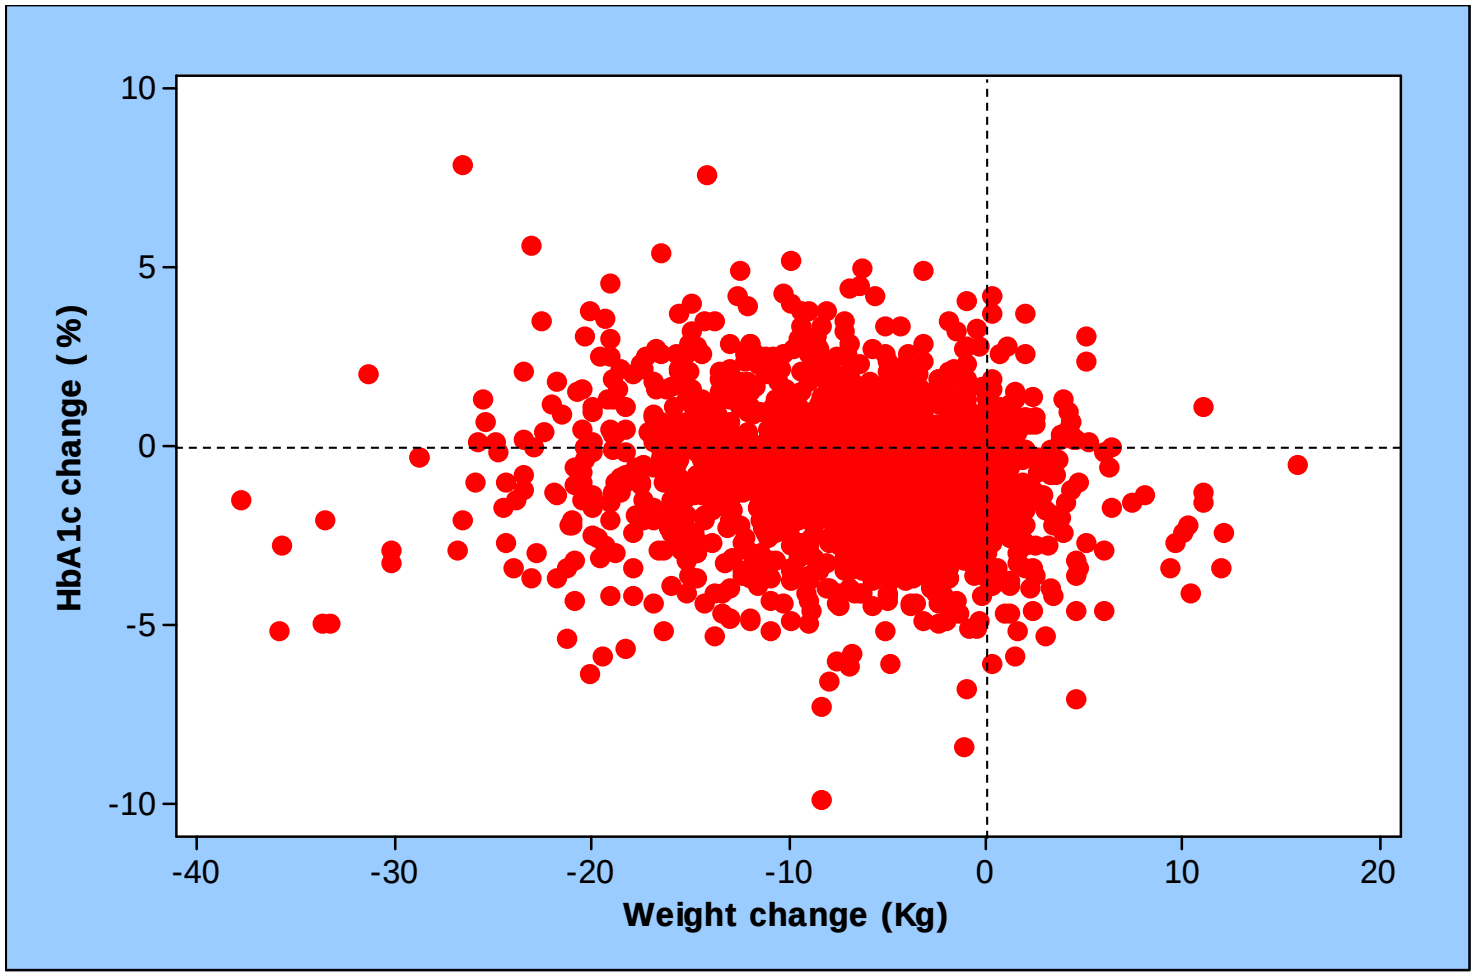
The family of incretin-based therapies



DPP IV inhibitors

- Comparable improvement in glycaemic control to SUs but with much less hypoglycaemia and weight neutral
- Useful in renal failure
  - Saxagliptin: renal dose 2.5 mg od
  - Linagliptin: biliary excretion, no dose adjustment needed
- CV outcome trials in progress

Exenatide – national audit



6 months after exenatide start in 1959 patients

Harrogate and District NHS Foundation Trust

Exenatide in real clinical use - conclusion

- 60% of patients achieve the ideal of both weight loss and fall in HbA1c
- However many patients experience a predominant response to only one of weight or HbA1c with more minimal response to the other
- Hence only 28% achieve the NICE guideline
- The NICE guideline should change to acknowledge that significant weight loss or significant HbA1c response may represent a beneficial response

Composite end points that matter

HbA_{1c} <7.0%

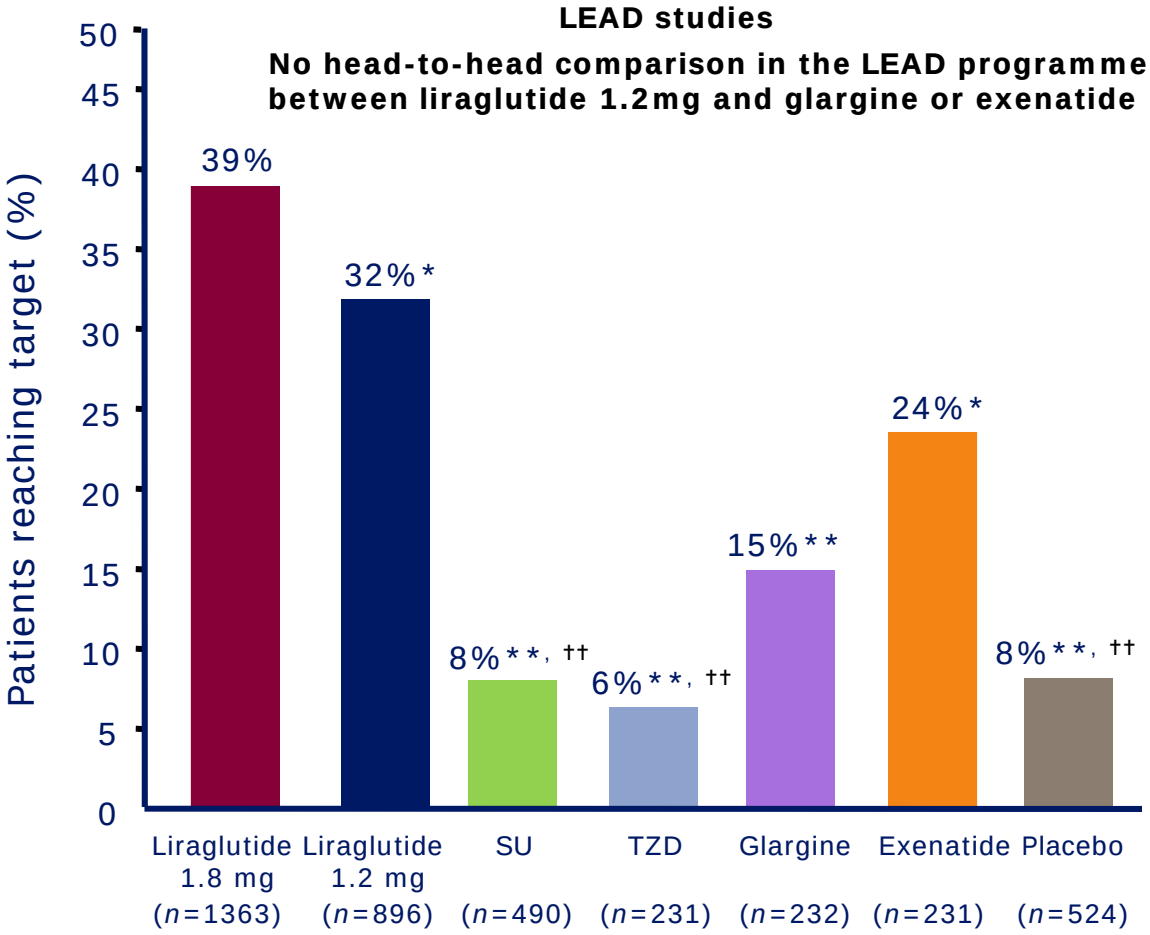
+

No weight gain

+

No hypoglycaemia

Composite endpoint: HbA_{1c}<7.0%, no weight gain and no hypos



Liraglutide 1.8 mg is superior (*p<0.01; ** p<0.0001)
Liraglutide 1.2 mg is superior (†† p<0.0001)
Percentages are from logistic regression model adjusted for trial, previous treatment and with baseline HbA_{1c} and weight as covariates

Long vs short-acting GLP 1 agonists

- Advantages:
  - Better glycaemic control
  - Better tolerated
  - ?Better adherence
- Disadvantages:
  - ?Less weight loss
  - Slower onset of action
  - More difficult to stop

GLP1 agonists and insulin

GLP1 and insulin – case study

- PC, 52 M
- Jan ’10: wt 135.6 kg HbA1c 86 mmol/mol (10.0%)
  - On 256 units insulin/d
  - Started liraglutide: titrated to 1.8 mg od
  - Treatment costs injectable therapy £5.84/day
- April ’11: wt 129.0 kg HbA1c 62 mmol/mol (7.8%)
  - On 68 units insulin/d
  - Treatment costs injectable therapy £5.69/day

NPH/isophane insulin should be first choice for initiation in type 2 diabetes

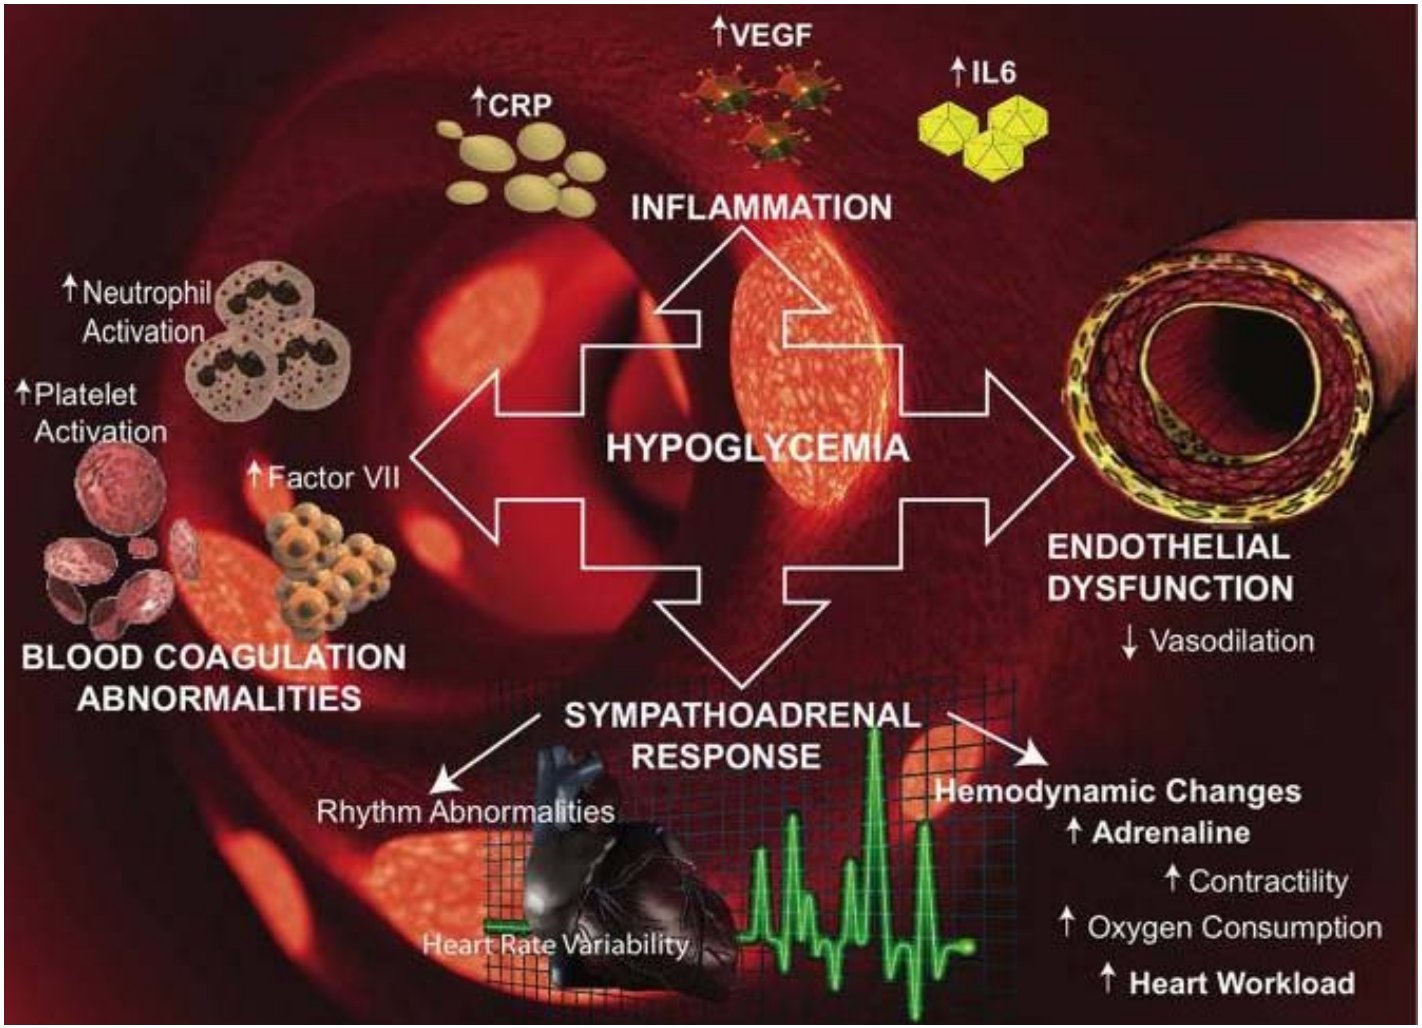
Pathophysiological cardiovascular consequences of hypoglycaemia



CRP, C-reactive protein; IL-6, interleukin 6; VEGF, vascular endothelial growth factor

Desouza *et al. Diabetes Care* 2010;33:1389–94

Hypoglycaemia in clinical practice

- 3% of people with type 2 diabetes experienced severe hypoglycaemia over a 12 month period
- People of all ages who experienced severe hypoglycaemia had a 79% increased risk of suffering an acute cardiovascular event
- Hypoglycaemia directly preceded an acute cardiovascular event in over 25% of people
- People who experienced severe hypoglycaemia incurred a 2 fold greater health related expenditure

Johnston et al. Diabetes care March 2011

Nocturnal hypoglycaemia

- Almost 50% of all episodes of severe hypoglycaemia occur at night during sleep[1]
- Nocturnal hypoglycaemia is a major concern to patients and family, and is a particular barrier to insulin dose titration[2,3]
- Nocturnal hypoglycaemia has a major detrimental effect on mood and well being the following day[1]
- Nocturnal hypoglycaemia is linked to 'dead in bed' syndrome[4]
- Recurrent nocturnal hypoglycaemia is linked to development of hypoglycaemia unawareness[5]
- Avoiding nocturnal hypoglycaemia is a key clinical imperative

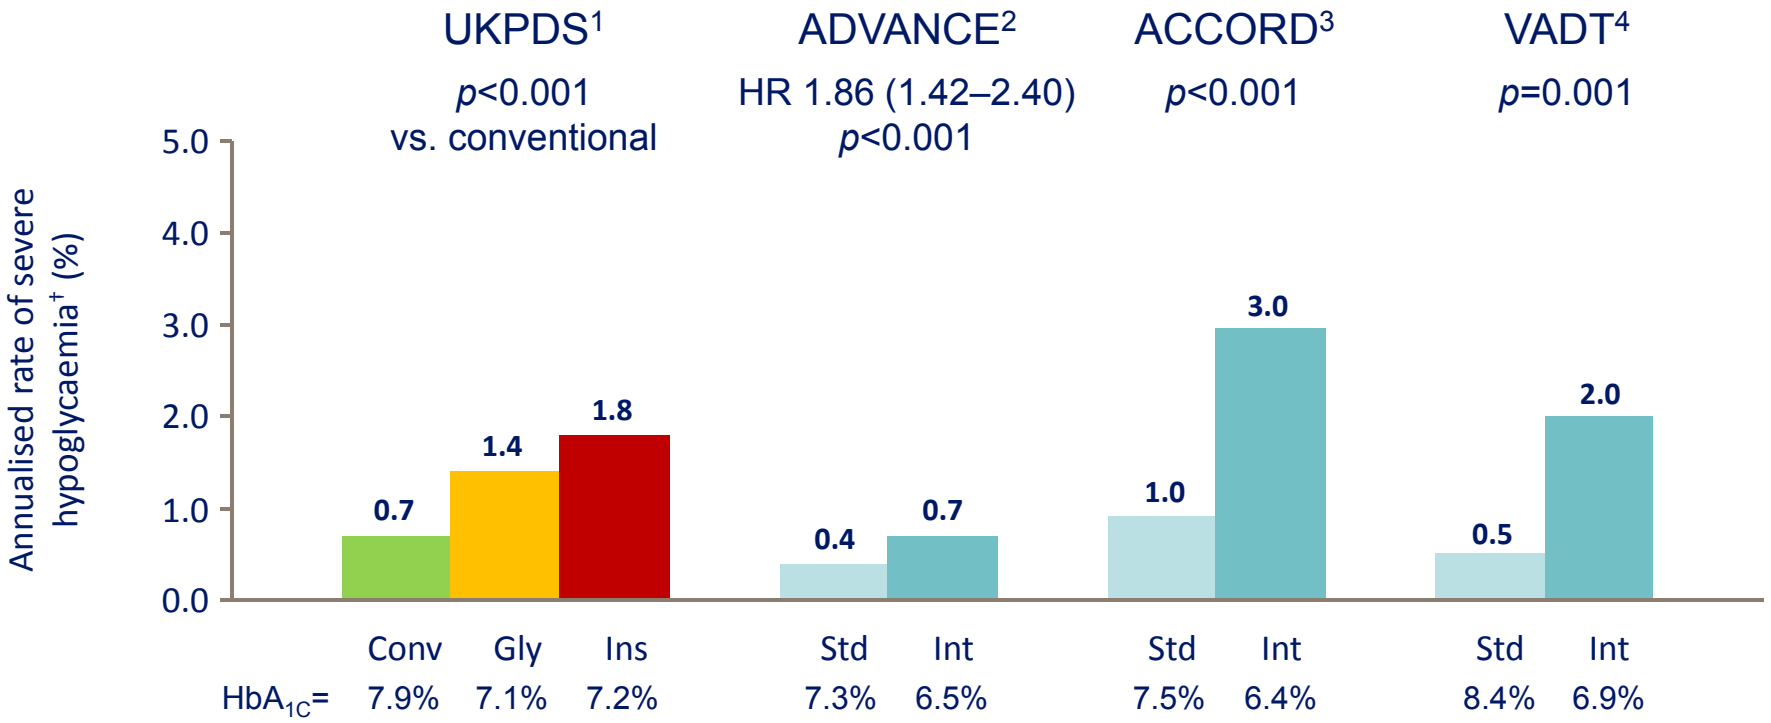
Consequences of hypoglycaemia for driving in the UK

Patients managed by insulin, **must** inform the DVLA of their treatment and **also if the following apply**:

- You suffer more than one episode of disabling hypoglycaemia (low blood sugar) within 12 months, or if you or your carer feels you are at high risk of developing disabling hypoglycaemia
- You develop impaired awareness of hypoglycaemia (difficulty in recognising the warning symptoms of low blood sugar)
- You suffer disabling hypoglycaemia while driving

DVLA guidance. Available at: http://www.dft.gov.uk/dvla/medical/ataglance.aspx

Higher rate of severe hypoglycaemia with intensive glycaemic control*



*Intensive glycaemic control was defined differently in these trials. †Hypoglycaemia requiring any assistance in glucose-lowering trials. Conv, conventional therapy; Gly, glibenclamide; HbA_{1c}, glycated haemoglobin; HR, hazard ratio; Ins, insulin; Int, intensive therapy; Std, standard therapy

N Engl J Med* 2009;360:129–39

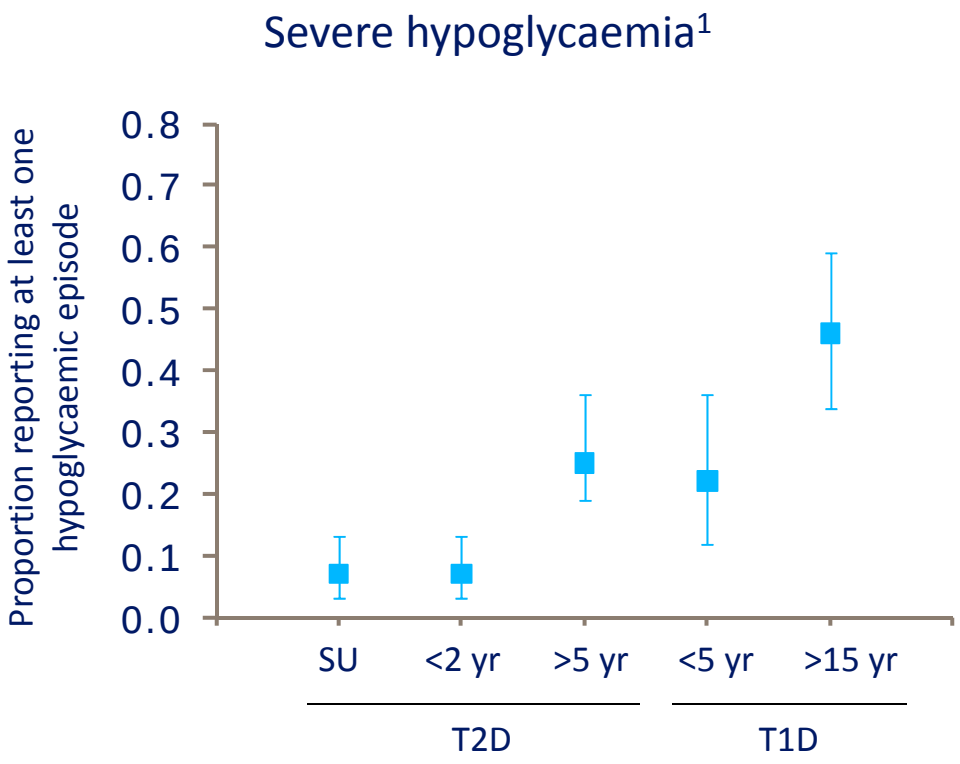
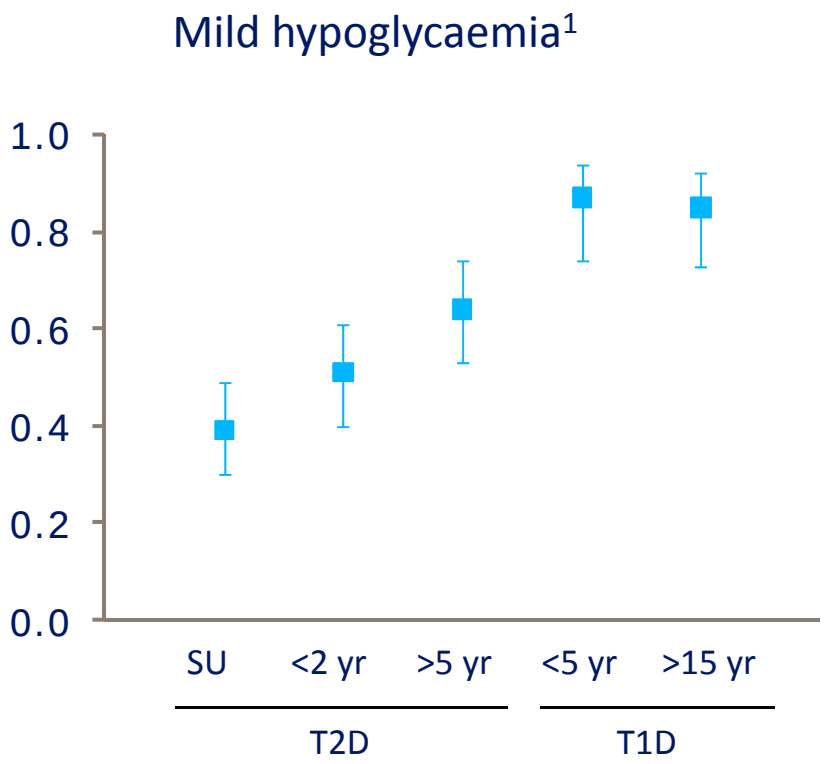
Myth 1: hypoglycaemia does not occur in T2DM





- T1D
  - 55% of severe and 43% of all hypoglycaemic episodes occur during sleep in T1D[2]
  - 36% of severe episodes that occurred while awake had no warning signs[2]

SU, sulphonylurea

[1]UK Hypoglycaemia Study Group *Diabetologia* 2007;50:1140–7;
[2]DCCT. *Am J Med* 1991;90:450–9

Myth 2: hypoglycaemia does not have major consequences in T2DM

- Similar clinical (CV and neurological) consequences to T1D

However:

- T2D population is older
  - Symptoms can be different
  - Hypoglycaemia unawareness
  - More comorbidities
    - high frequency of CVD
    - osteoporosis – higher fracture risk
    - longer hospital stay duration
- Event rate increases with disease duration – progressive disease

CV, cardiovascular; CVD, CV disease

Bullet Points for New Clinical Solutions

- There is a legacy effect of good glycaemic control so NICE targets are essential and combination drug therapy is inevitable
- The ideal drug combination therapy for glucose control combines low risk of hypoglycaemia, weight reduction and CV safety
- Newer agents, particularly those targeting the GLP1 receptor show potential but CV safety data is awaited
