This paper offers a formal analysis of grammaticalization and language change in the framework of generative grammar, focusing on change involving speech verbs, which is robustly attested cross-linguistically (see e.g. Lord 1976, Klamer 2000, Roberts & Rousseau 2003). E.g. in (1), kong in Taiwanese is originally a speech verb (1a), but it can now also be used as a complementizer (1b). I also discuss relevant multifunctional items (which can function as e.g. speech verbs, complementizers, quote introducers, evidential markers), relating them to the language change in (1).

(1) a. Ahui kong Asin m lai  b. Ahui siong kong Asin m lai
   ‘Ahui said Asin is not coming.’  ‘Ahui thought that Asin was not coming.’

say to C. Descriptively, (1) is a case where a speech verb has become a complementizer keeping its phonological shape the same. To capture this, I assume that speech verbs, in fact verbs in general, consist of (at least) two components; an acategorial component which encodes its semantic and phonological information, and a verbalizer component (e.g. Halle & Marantz 1993, Pesetsky 1995, Marantz 1997; the root-&-category theory). Under the root-&-category theory, speech verbs have the structure in (2a). In (2a), the category neutral speech root takes its complement (see Harley 2014), and it is merged with the verbalizer v. It obtains its lexical categorial status due to the v.

(2) a. [[Subj] [CP/quotation] \$SPEECH\ v]  b. [[CP/quotation] \$SPEECH]
I suggest that the grammaticalization from speech verbs to complementizers involves detachment (or loss) of the verbalizer component, as in (2b). What is left in (2b) is the acategorial element \$SPEECH\; it has the phonological and semantic information of “speech”, but does not have a lexical categorial status due to the absence of a category-defining head. I suggest that this acategorial element is reanalyzed as a functional item, in order to be legible to the system of the grammar; roots cannot appear (cannot be pronounced or interpreted) without being categorized by merging syntactically with category-defining heads (e.g. Embick & Marantz 2008). Also, since \$SPEECH\ is located immediately above C (or a sister to CP), it gets reanalyzed as an item in the C-domain, such as a complementizer or an evidential marker (see below).

Full verbal structure: (2a). Apart from unmarked speech verbs, I suggest that toiu in Japanese, which is typically treated as a complementizer, is actually the case of (2a), which, as we will see below, facilitates the change to (2b). As in (3), toiu appears in complex nouns. However, as Saito (2017) shows, it is morphologically complex; it consists of to ‘C’ and uu ‘say-Pres’ (see also Lord 1976). E.g., it is possible to inflect uu in toiu as if it is a normal speech verb, as in (4). Even if (3) involves a true speech verb, we can still capture the interpretation; (3) means ‘the rumor which says that John will come’. As we see later, some items are both in this stage and the stage (2b).

(3) John-ga ku-ru toiu uwasa  (4) John-ga ku-ru toitta uuwasu
   John-Nom come-Pres TOIU rumor John-Nom come-Pres -Past rumor
   ‘the rumor that John will come’  ‘the rumor that John will come’

Detachment of v: (2b). In (2b), the verbalizer is detached from \$SPEECH\ and the root loses its lexical categorial status. Still, \$SPEECH\ introduces a direct and/or indirect quotation as an item encoding information about speech, just like speech verbs do, because speech verbs also involve \$SPEECH\. I suggest that the structure in (2b) is responsible for the semantic bleaching of speech verbs. Klamer (2000) suggests that grammaticalization of speech verbs to complementizers involves loss of the argument structure of speech verbs (specifically, loss of an external argument). In (2b), assuming that v introduces an agent (cf. Chomsky 1995, Harley 1995), the agent of the speech (= the external argument introduced by v) is absent in (2b). The items which are originally speech verbs are semantically bleached in that they do not require agentive arguments. Hence, (2b) can be seen as an implementation of Klamer’s idea under the root-&-category theory. I further suggest that the structure in (2b) differs from true speech verbs in that it loses an event interpretation due to the absence of v, assuming that v encodes eventivity (e.g. Embick 2004), i.e., (2b) does not require an actual speech event in the interpretation. This is another type of semantic bleaching. I suggest that an instance of (2b) is kua in Tukang Besi. Kua is a complementizer derived from a speech verb, but its predicative use is obsolete now (Klamer 2000). I also suggest that tte in Japanese is in this stage. Tte has developed from toiu (see above) via phonological contraction (see Lord 1976), but tte and toiu are syntactically different. E.g. tte can co-occur with another speech predicate as C, while toiu cannot (5). Tte works as C so that it can co-occur with another speech predicate while toiu has a full verbal structure as argued above, so it cannot appear in the C-position.

(5) John-ga Mary-ni [sukida]-{*toiu/tte} itta
   John-Nom Mary-Dat like-TOIU/TTE said
   ‘John said to Mary that he likes her.’
It is also widely attested that evidential particles have developed from the combination of the verb ‘say’ and C, e.g. *dizque* in (some American) Spanish, *dicira* in Sicilian, *nachi* in Sardinian (Kany 1994, Cruschina & Remberger 2008). I argue that these particles have developed from (2a) to (2b); in this case, the combination of C and √\textsc{speech} is reanalyzed as one item. Even though they look morphologically complex (i.e. say+C), they behave as single functional particles, e.g. phonological reduction, impossibility of inflection, semantic bleaching (Cruschina & Remberger 2008, *tie* in Japanese can also function as an evidential marker, see e.g. Ishii 2015). Despite their functionalized status, they still encode the information of speech due to √\textsc{speech}, which, together with C, has been reanalyzed as a functional item; this is why they mark evidentiality. An interesting case is *kong* in Taiwanese (1) and *fen(e)* in Buru (Simpson & Wu 2002, Klamer 2000); these items can be used as speech verbs as well as C co-occurring with other speech/thought predicates; I suggest that they are now in the stage in (2a) and (2b).

\textsc{speech} + non-v categorizer. In (2a), we assume that √\textsc{speech} is merged with v. Here, once we assume that speech verbs have a complex structure, the root plus the verbalizer, there are other logical possibilities regarding what √\textsc{speech} can be merged with. That is, we may expect to find cases where √\textsc{speech} is combined with non-verbal categorizers, such as a and n, as in (6).

(6) \[ [a, n, p] \]

What we would observe in such cases then is a non-verbal lexical element that introduces indirect and/or direct quotation. I argue that this indeed happens; non-verbal quotative items are cross-linguistically attested. I suggest that the morpheme teki ‘like’ in Japanese is an instance of (6). Teki usually takes a nominal complement to form an adjective (7a/b), but in its innovative use, it can take an (in)direct quote as its complement (7c). Saito (2017) argues that clause-taking teki has the structure in (8), where √\textsc{speech}, and a is spelled out as teki, which is exactly the same as (6). This is the case where a is merged with √\textsc{speech} (see Saito 2017 for evidence for √\textsc{speech} in this use of teki).

(7) a. sei\-i b. sei\-i-teki c. [wata\-si-ga iti\-ban kawa\-ii]-teki-na taido politics politics-Teki I-Nom most cute-Teki-Cop attitude

‘politics’ ‘political’ ‘an attitude like, “I’m the cutest.”’

(8) \[ [\{\{c, n\}\} \textsc{speech}] a \]

In fact, teki-phrase (boldfaced in (7c)) behaves as an AP. E.g., intensification and comparatives of the degree of similarity expressed by teki are possible (Saito 2017). Also, morphologically, teki-phrase shows the same conjugation pattern as adjectives (i.e., nominal adjectives, see Nishiyama 1999). I further suggest that it is possible to merge n with √\textsc{speech}. The attachment of n is attested in Italian. Italian *tipo* ‘type’ is usually an unmarked noun (9a), but in informal register, it can now be used as a quote introducer, as in (9b).

(9) a. il *tipo* di riso b. Ho detto *tipo* “Scordatelo!”

the TIPO of rice I told TIPO forget.it

‘the type of rice’ ‘I told you, “Forget it!”’

I argue that the use in (9b) is an instance of (6), where n is attached to √\textsc{speech}. Even though tipo is (originally) a noun, it can introduce a quote due to √\textsc{speech}.

What about p? Even though it is controversial whether p exists, if it does (cf. Svenonius 2010), I suggest that van in Dutch is the case of (6) where √\textsc{speech} merges with p. Van ‘of’ is originally a preposition (10a), but it has a “quotative” use (10b) (Coppen & Foolen 2012, Haddican & Zweig 2012).

(10) a. Dat boek is van mij b. Hij zei zoiets van “laat me geraust”

that book is VAN me he said such.something VAN leave me alone

‘That book is mine.’ ‘He said something like, “Leave me alone.”’

Consequences. The proposed analysis enables us to relate multifunctional items (functioning as e.g. C, quote introducers, speech verbs, evidential markers) to well-attested language change patterns. In the literature, it has been often assumed that grammaticalization involving speech verbs is limited to languages with serial verb constructions (e.g. Klamer 2000, Roberts & Rousseau 2003). However, this paper shows that the distribution of this type of change is much wider than the availability of serial verb constructions, in line with Lord (1976). In fact, the proposed analysis does not rely on any property of serial verb constructions; the relevant change results from detachment of categorizers. The paper provides a new way to investigate quotative constructions and relevant multifunctional items within a bigger picture, i.e. language change involving speech roots.
