

# Approaching Actuation

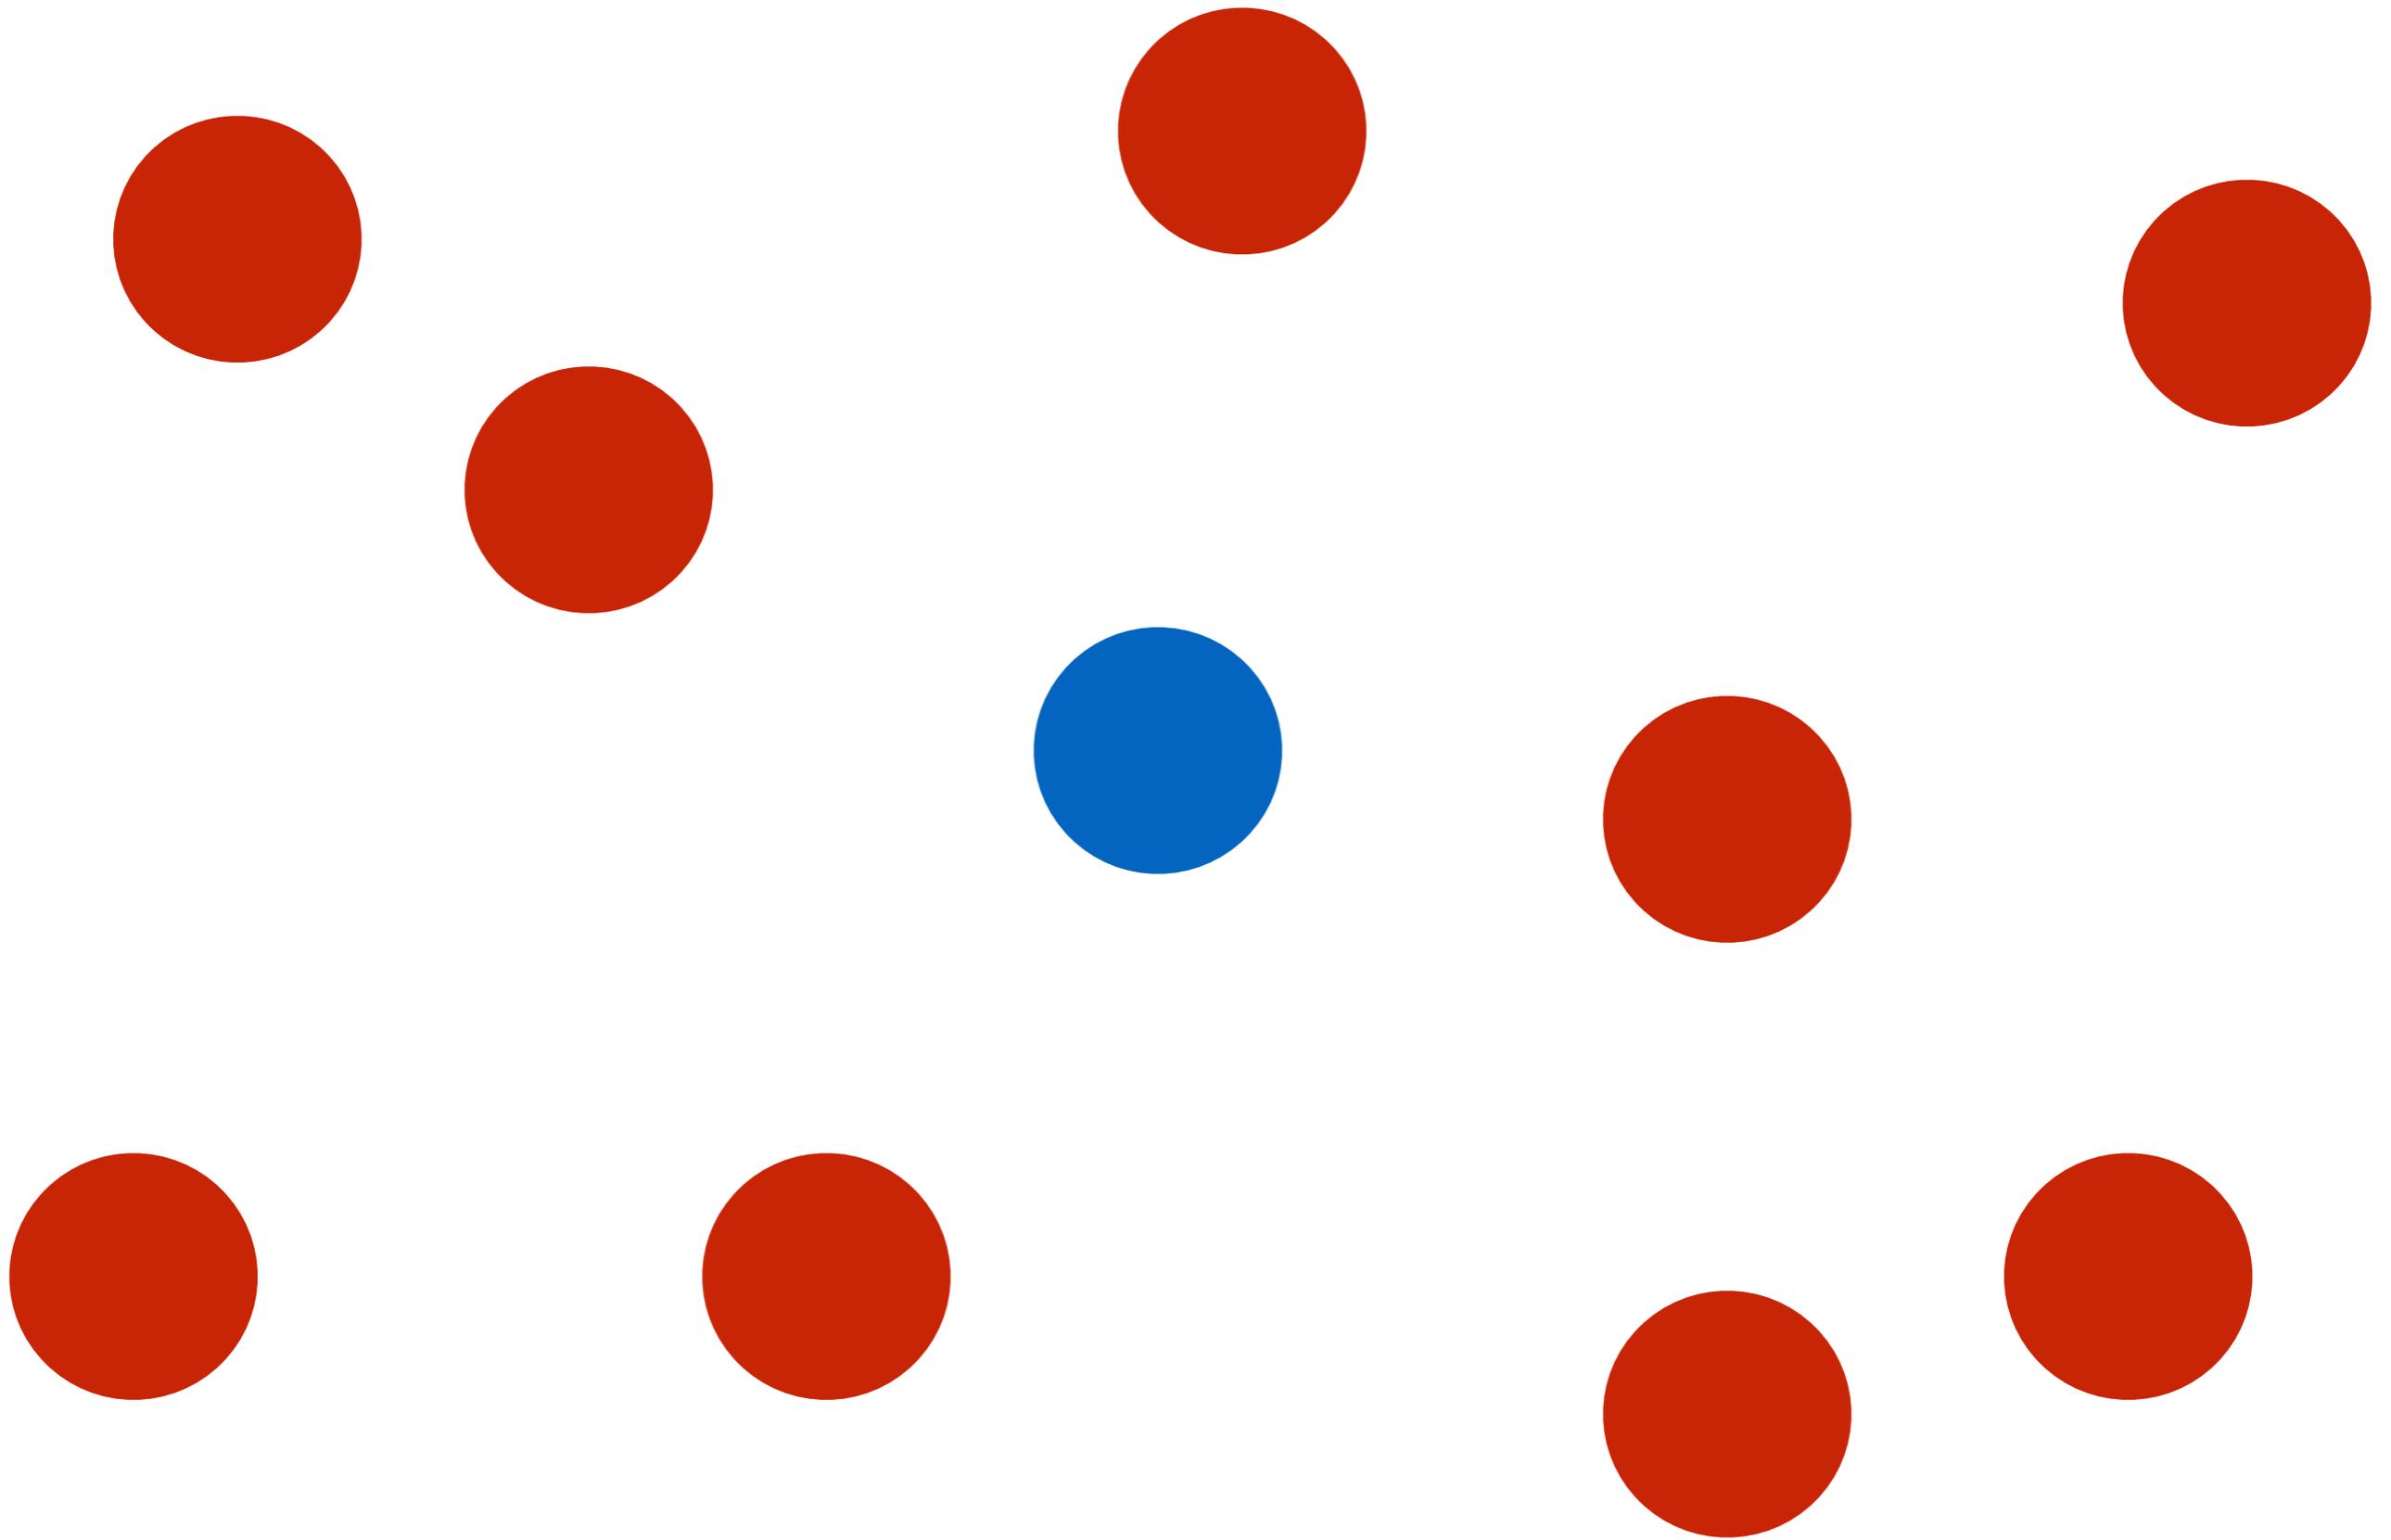

Charles Yang  
University of Pennsylvania

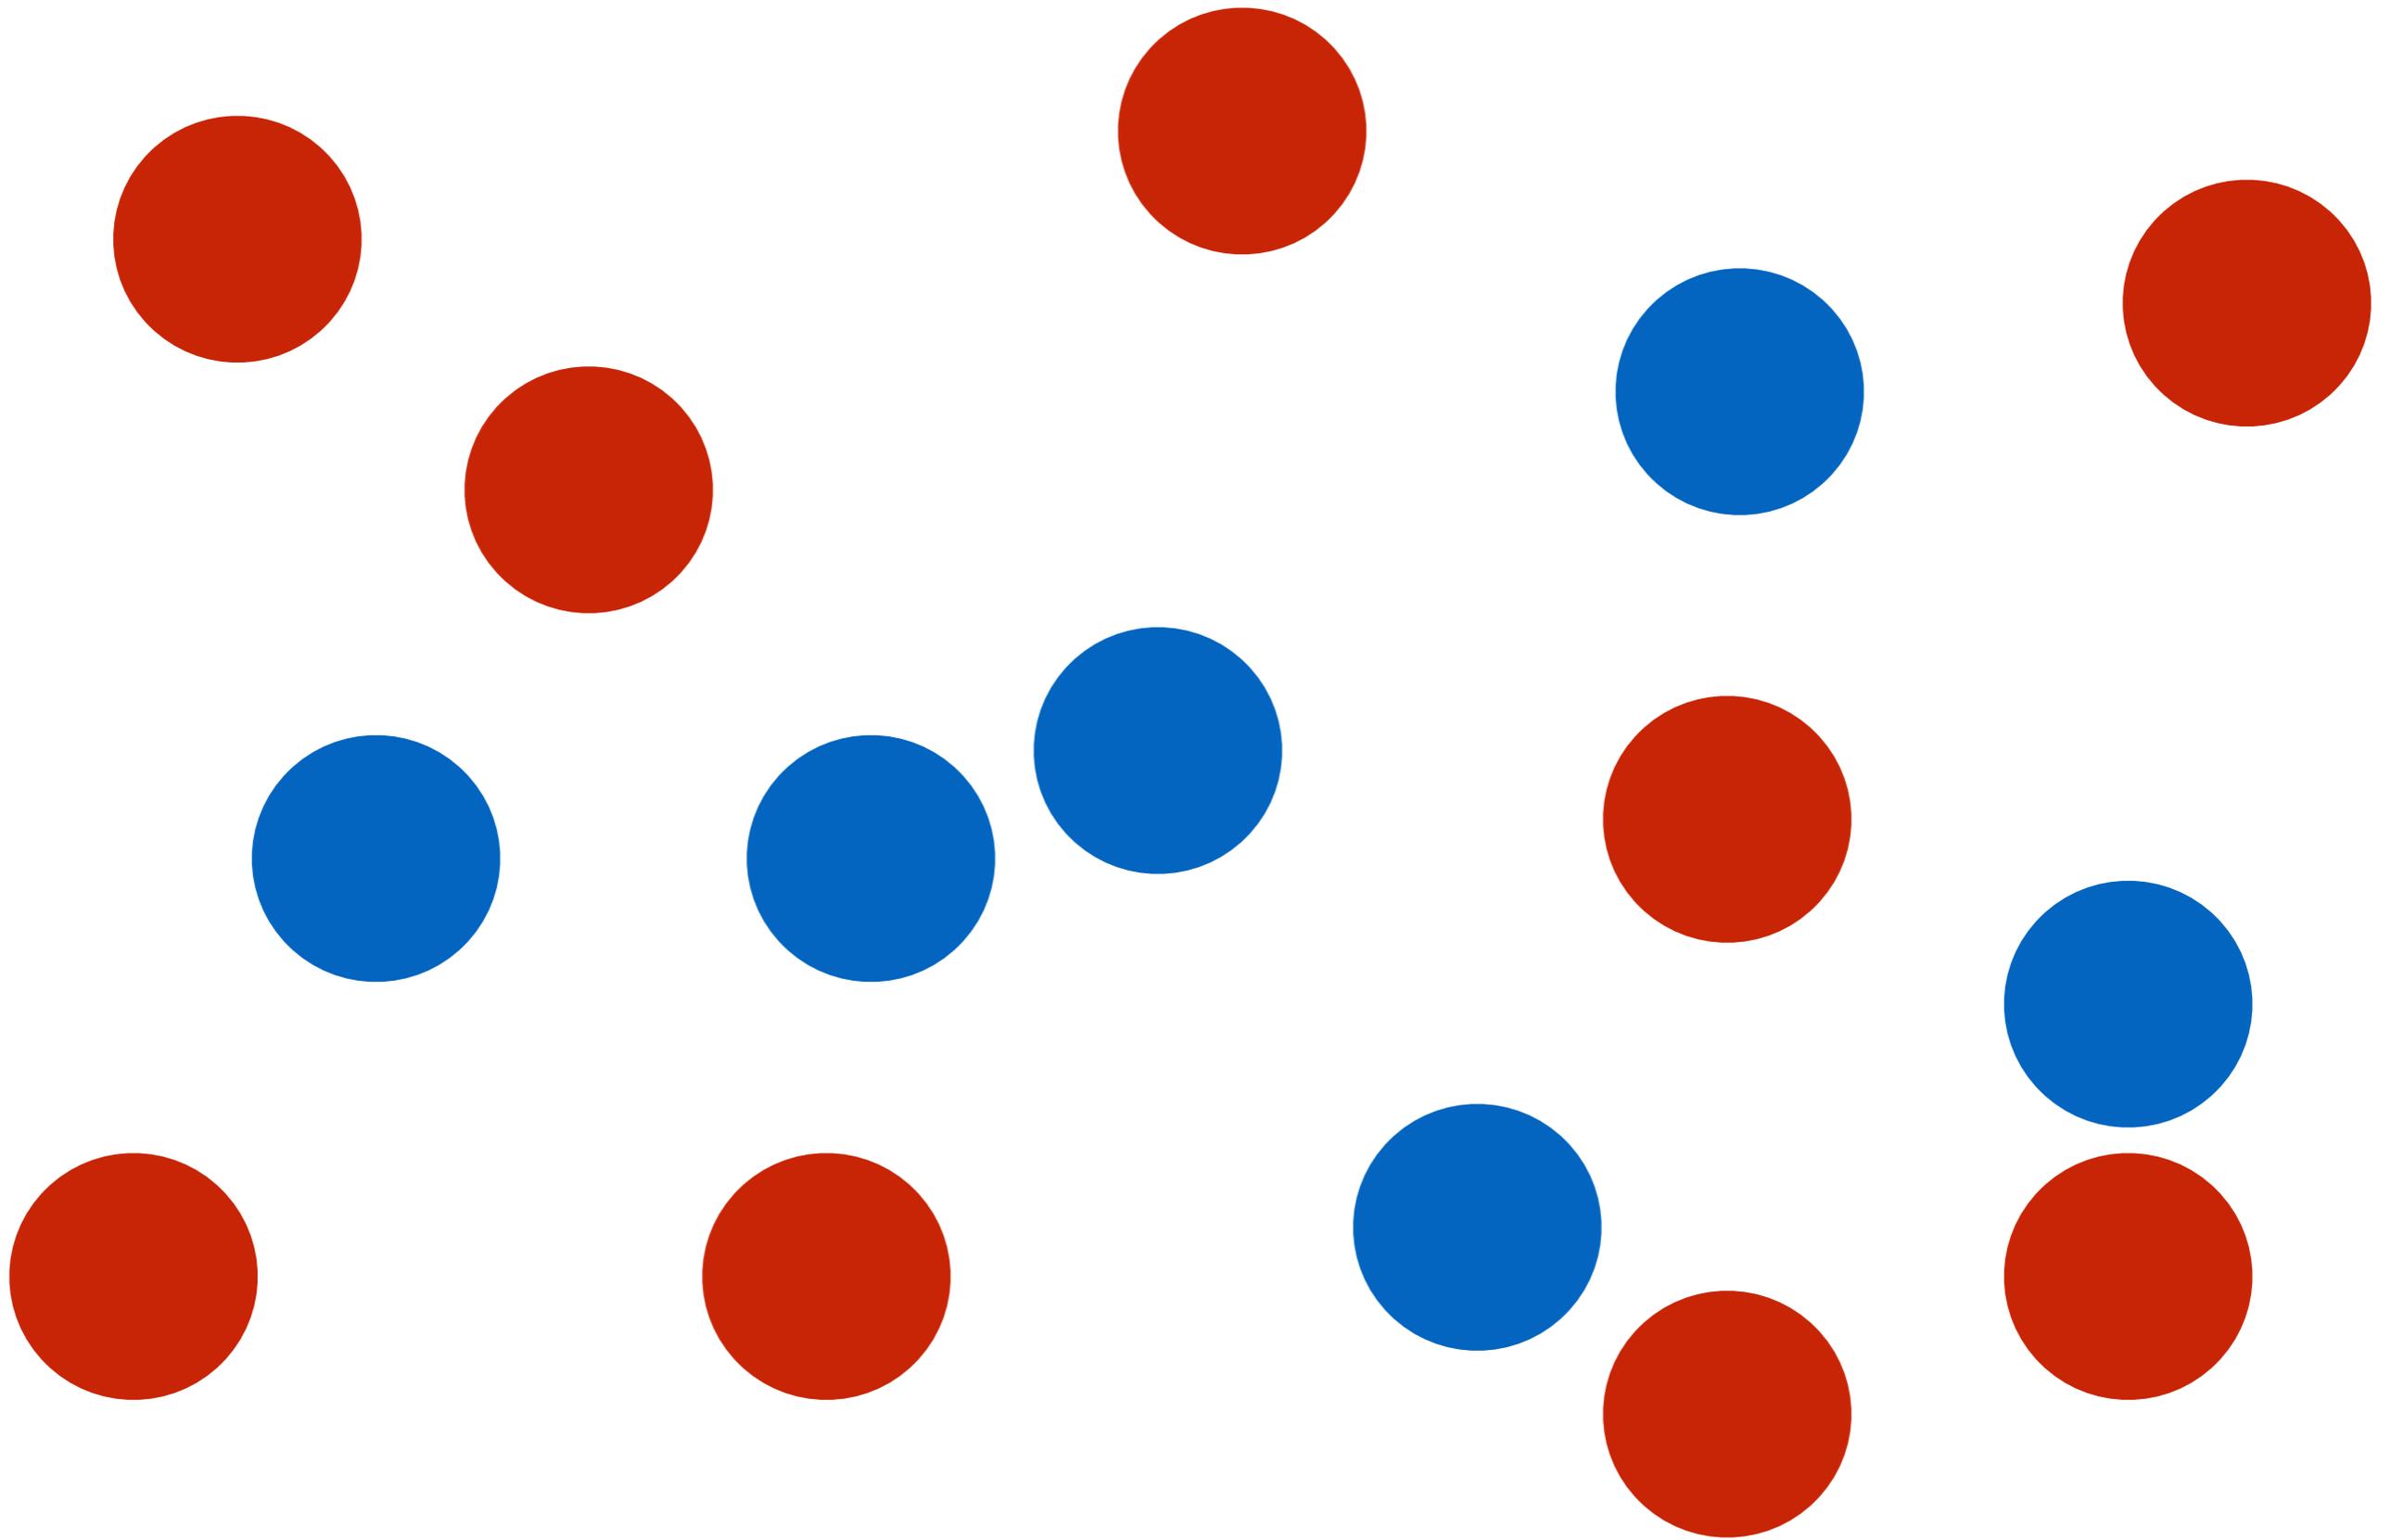

University of York, Feb 2015

# Actuation

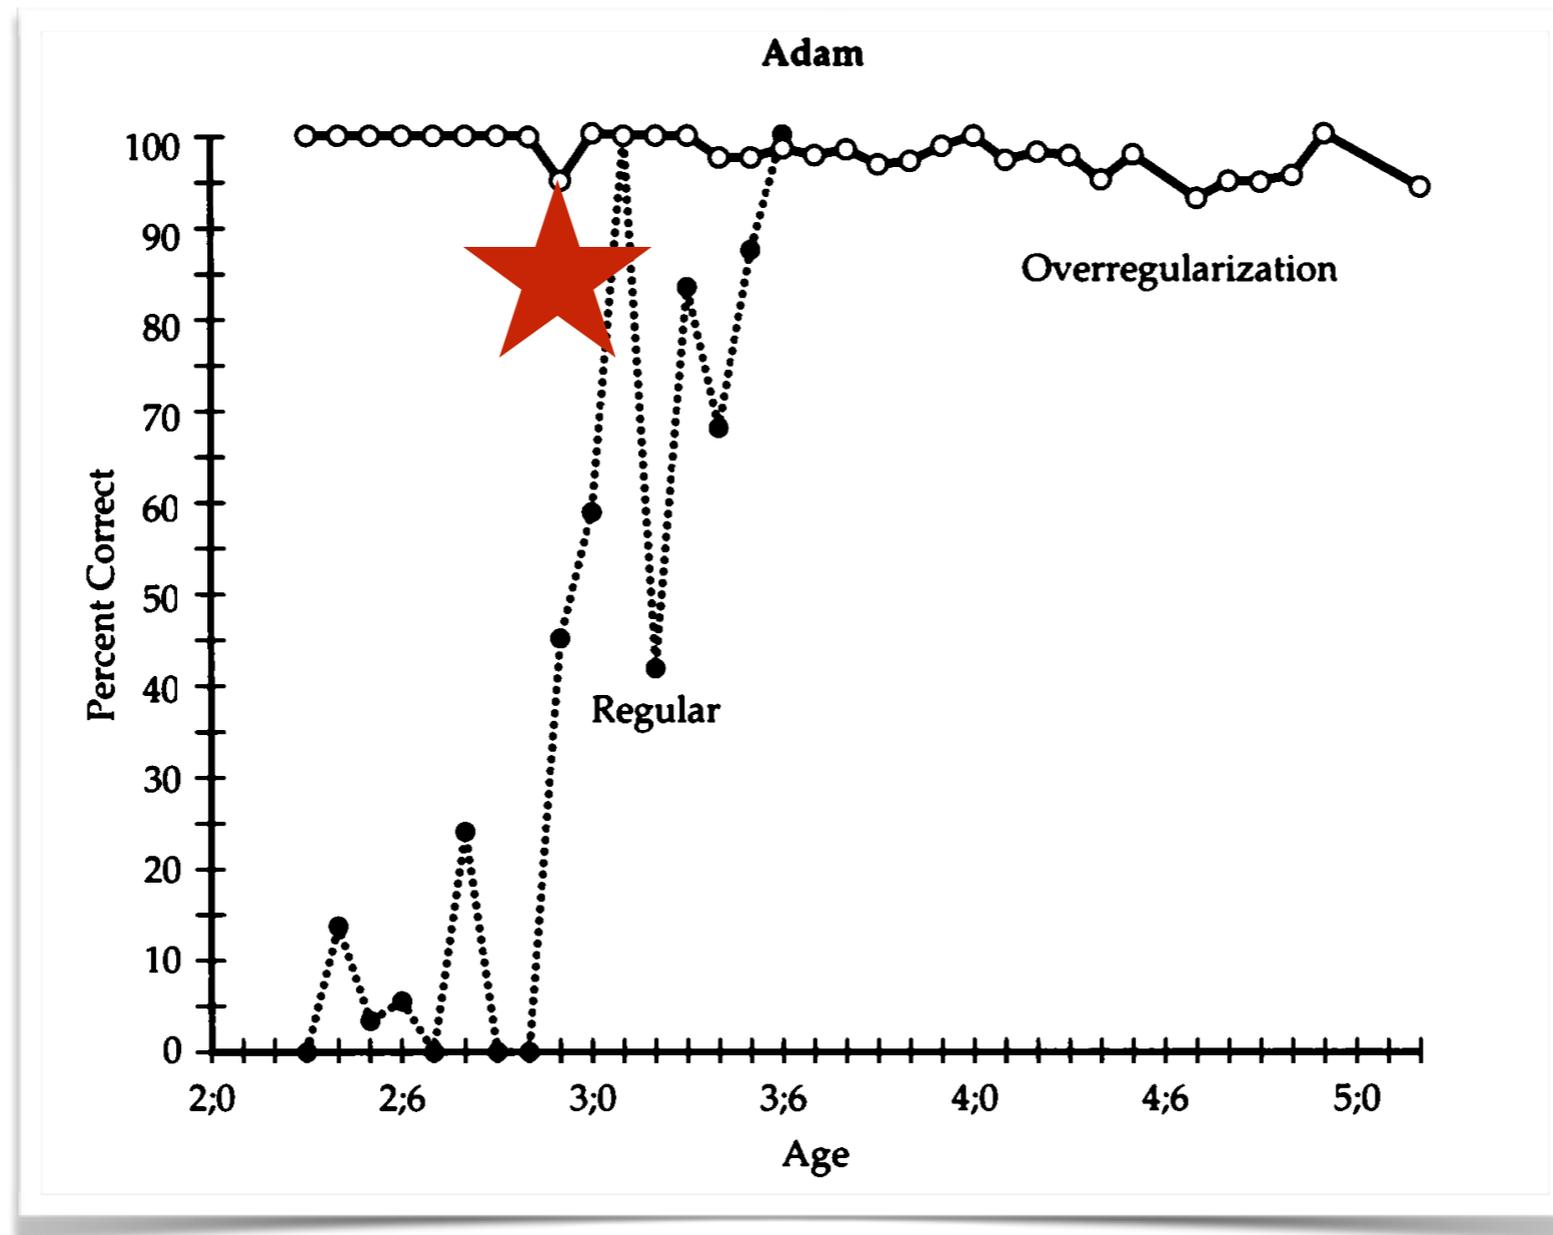

- Weinreich, Labov & Herzog (1968)
- Origin of linguistic variation:
  - “they are there all along”: e.g., the biological space of grammar (WLH’s constraints)
  - Arise from linguistic transmission (i.e. experience dependent learning and generalization)

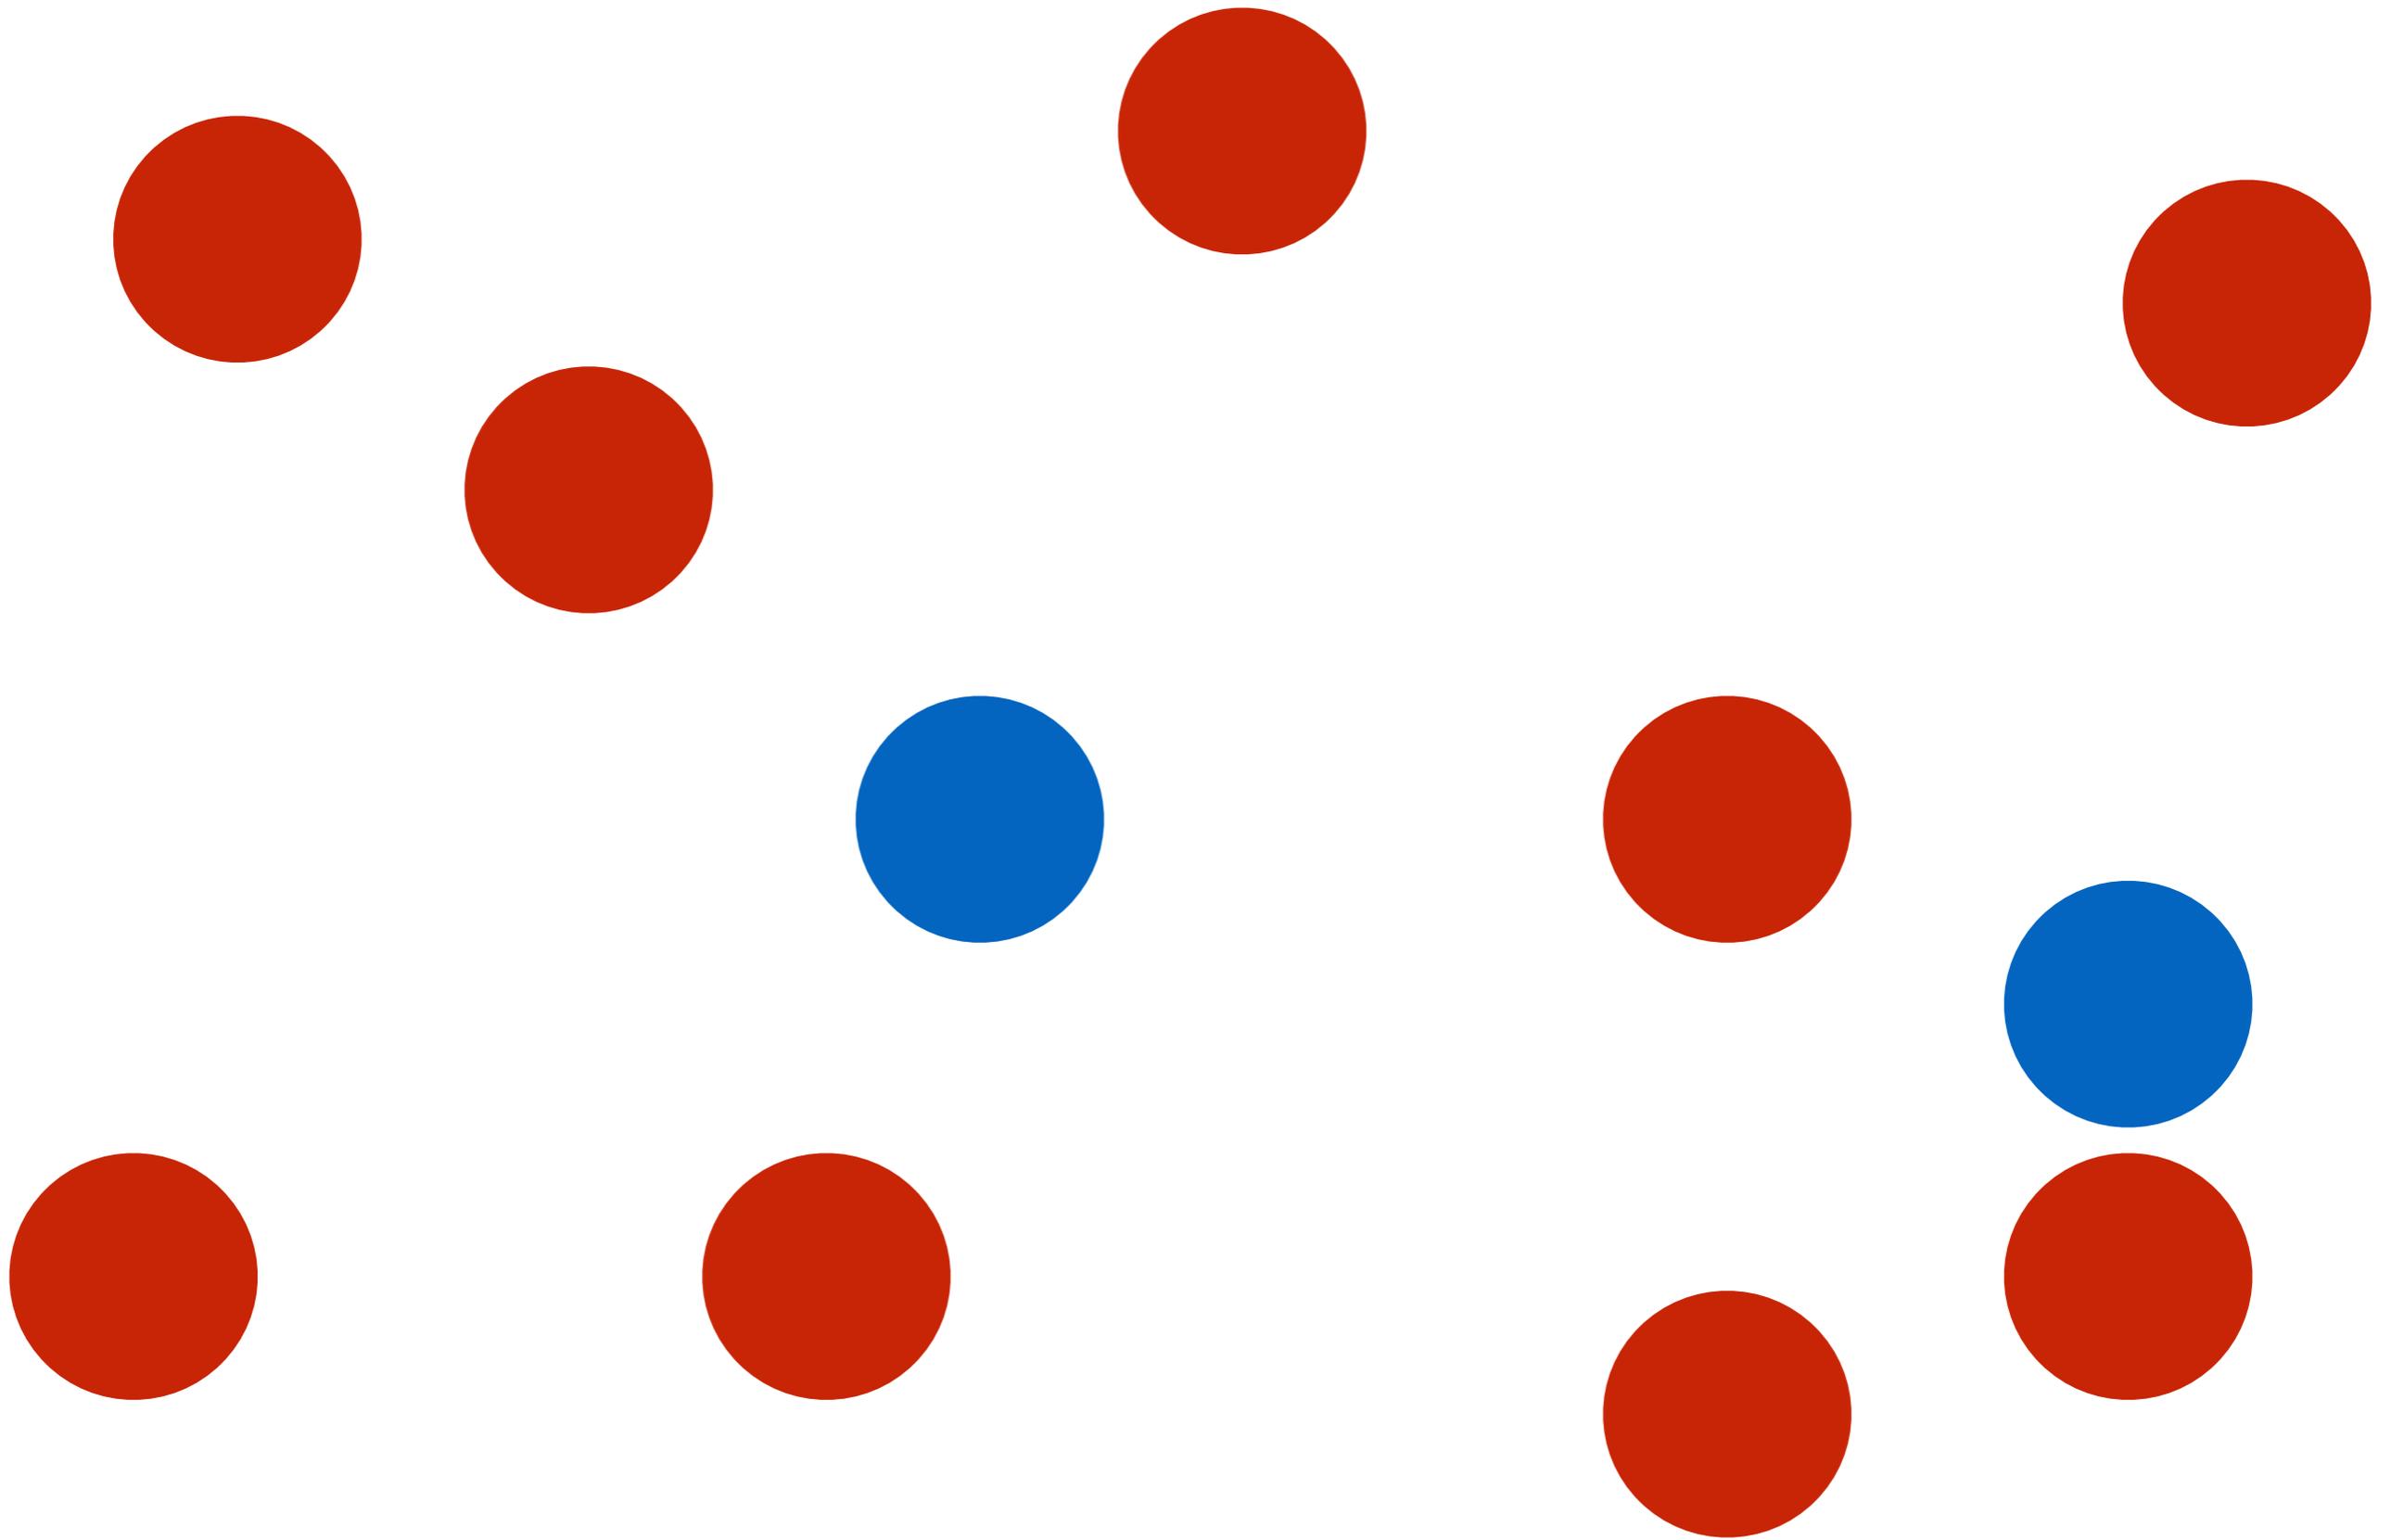

# Tipping Point

“Add -d” is not an innate UG option!

# How to Generalize

- Let **R** be a rule applicable to **N** lexical items out of which **e** do not follow **R**. **R** is productive iff

$$e = \frac{N}{\ln N}$$

- The number of tolerable exceptions must be relatively small: otherwise the learner must lexicalize everything
  - English past tense:  $e = 120$ ,  $N$  must be greater than 800 for **-ed** to be productive
  - Emergence of “-d” as a productive rule takes place only after the child’s regulars overwhelm irregulars

# When Exceptions Overwhelm

- Polish **singular** masculine genitives take either *-a* or *-u* as suffix but neither seems to be the default based on a suite of tests (Dabrowska 2000).
  - **Plurals** take *-ow* as the default, with exceptional *-i/y* suffix
- Analysis of child-directed Polish in CHILDES

| suffix     | type freq. | productive? | ave. token freq. | error %       |
|------------|------------|-------------|------------------|---------------|
| -a (sg.)   | <b>837</b> | <b>no</b>   | 7.17             | 1.28%         |
| -u (sg.)   | <b>516</b> | <b>no</b>   | 8.8              | 0.24%         |
| -ow (pl.)  | <b>551</b> | <b>yes</b>  | 6.5              | 0.41%         |
| -i/y (pl.) | <b>61</b>  | <b>no</b>   | 11.4             | <b>15.53%</b> |

# Parameters and Exceptions

une *vieille* amie ‘a friend for a long time’

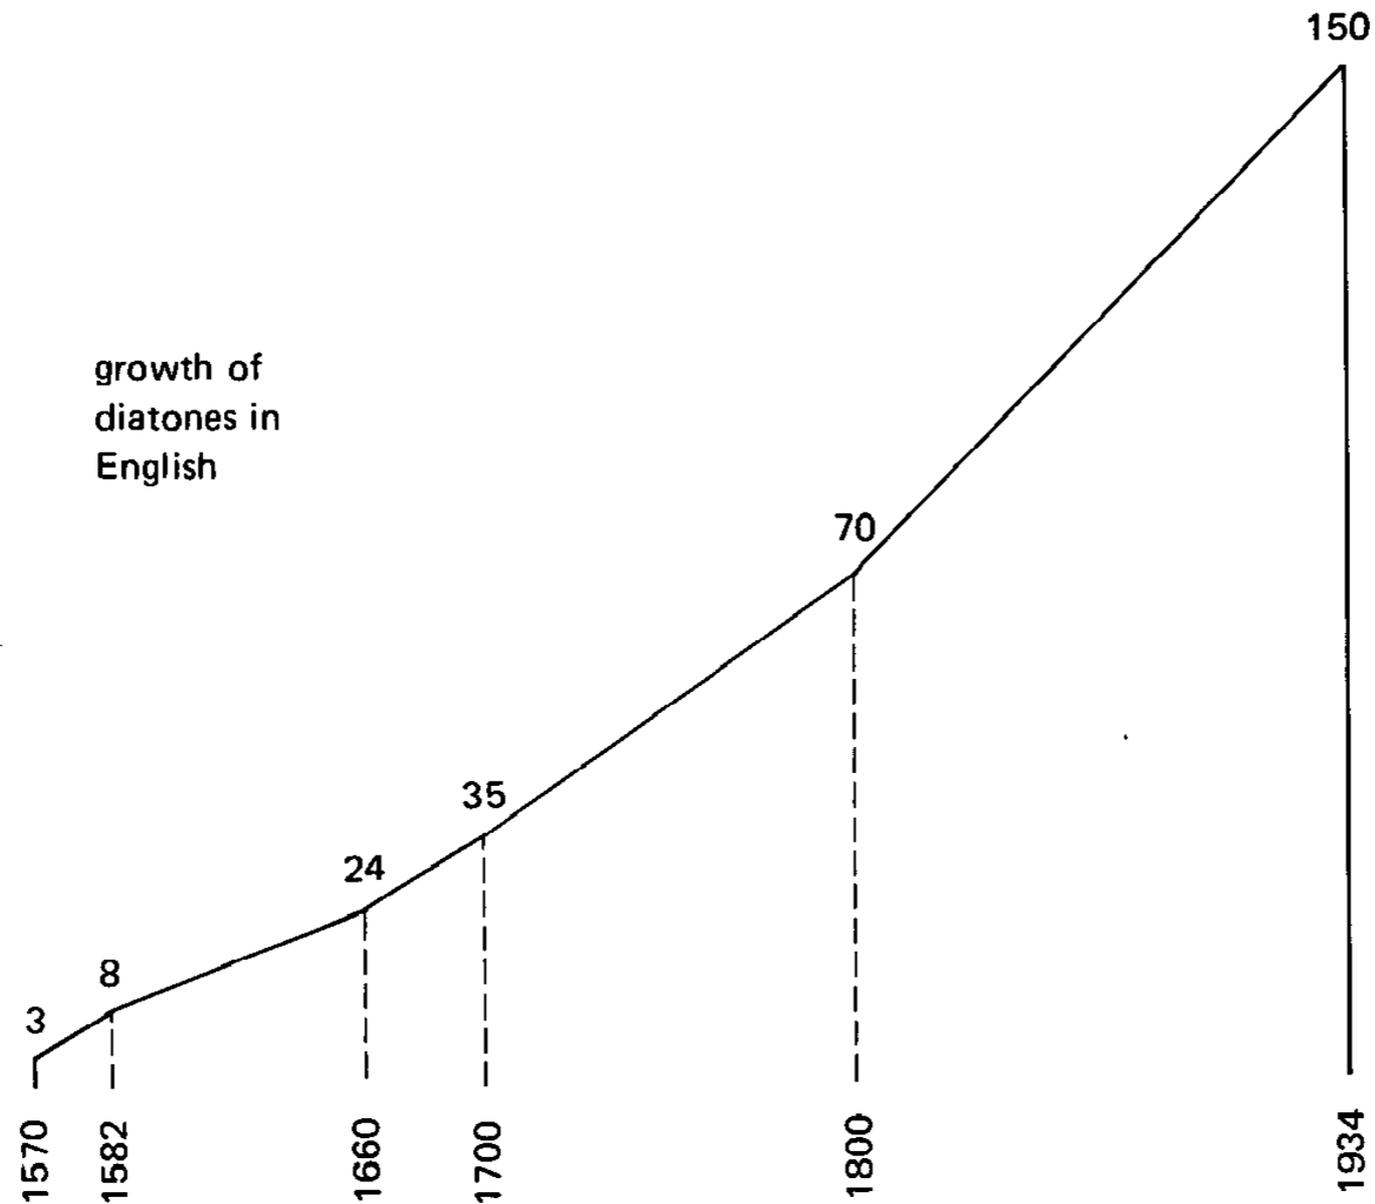

une amie *vielle* ‘a friend who is aged’

- Newmeyer (2004): parameters are wrong because they have exceptions
- A 200,000 word French directed corpus; adjectives tagged and lemmatized
- 20 exceptional adjectives
- 120 “regular” adjectives: 80 would suffice
- The default parameter value (or rule) can be maintained and the rest are lexicalized

# Two case studies

- The learner creates systematic regularities which lead to change
- **PER**mit (noun) vs. per**MIT** (verb): diatonic stress
- Dative alternations
  - John donated a painting to the museum
  - \*John donated the museum a painting

# Diatonic Stress

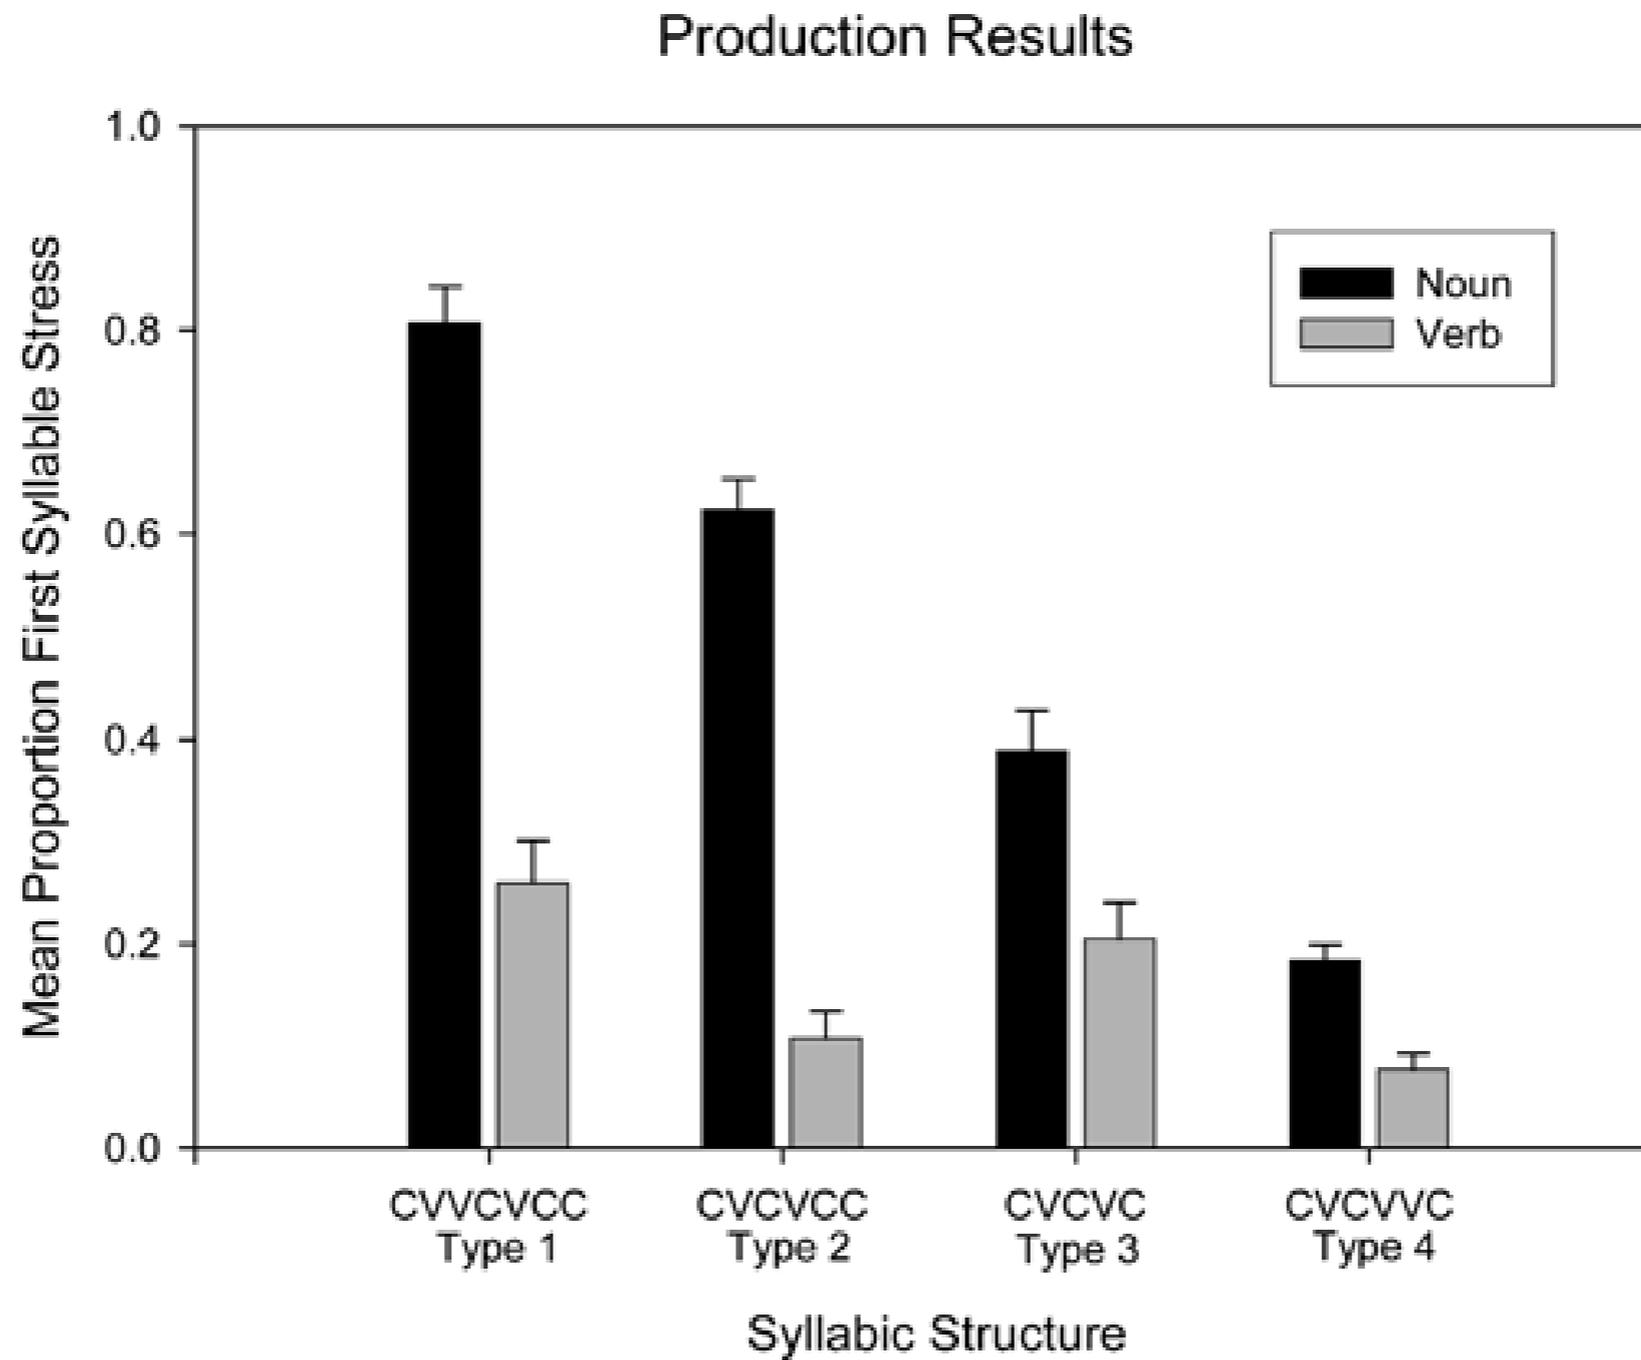

| N-V pairs    | Total | Isotonic | Diatonic | % of Diatones |
|--------------|-------|----------|----------|---------------|
| Disyllabic   | 1315  | 1165     | 150      | 11            |
| Polysyllabic | 442   | 372      | 70       | 16            |
| Total        | 1757  | 1537     | 229      | 13            |

Sherman (1975)

# English Stress

- The majority (>80%) of words are stress initial (Cutler & Davis 1987)
- Over 90% of bisyllabic nouns are trochaic, and about 70% of bisyllabic verbs are iambic (Bock & Kelly 1988)
- But English stress system is **not** a simple rule with 10% of exceptions

# Bisyllabic Nonce Words

# Previous Work

- A paradigm case for **lexical diffusion** (Wang 1969 etc.)
  - Language change proceeds on a word by word basis, rather than through a systematic grammar
  - Heavily influenced the phylogenetic approach to language classification
- The role of frequency: Words (N/V pairs) with lower frequencies tend to change first (develop diatonic stress first; Phillips 1984, Bybee 2002, Lieberman et al. 2007)

# Theories of English Stress

- Halle (1998):  $\sigma_1$   $\sigma_2$
- Nouns
  - If  $\sigma_1$  has VV or VC+ then it's stressed (kingdom, beetle)
  - Else if  $\sigma_2$  has VV then it's stressed (device)
  - Else  $\sigma_1$  is stressed (atom)
- Verbs
  - If  $\sigma_2$  has VV or VCC+ then it's stressed (revise, eject )
  - Else  $\sigma_1$  is stressed (ambush)

# 14% vs. 6%

- Legate & Yang (2012: Tribute volume for Carol Chomsky)
- Words that appear at least once per million in child directed English (excluding proper names): 5763
- Initial stress: 4960 (**14%** exceptions): above threshold
- Halle (1998): 5408 (**6%** exceptions): below threshold
- Only the Halle (1998) account can **productively** tolerate the amount of exceptions

# Hypothesis

- Diatonic stress shifts for words that are **predicted** to have divergence N/V stress
- **(1, 2): construct**
- (1, 1): ambush
- (2, 2): amount
- **(1, 2): reject**
- (1, 1): whisper
- **(2, 1): 🙈 (Sherman 1975, Sonderegger & Niyogi 2013)**

# Data

- CELEX homographic N/V pairs
- CMU Pronunciation Dictionary to obtain diatonic pairs
- SUBTLEXus corpus for word frequencies
- Halle (1998) predicts whether a specific N/V should shift or not
- 781 multisyllabic N/V pairs, 90 are diatonic (11.5%)
- 668 bisyllabic N/V pairs, 85 are diatonic (12.7%)

# Predicting Diatonics

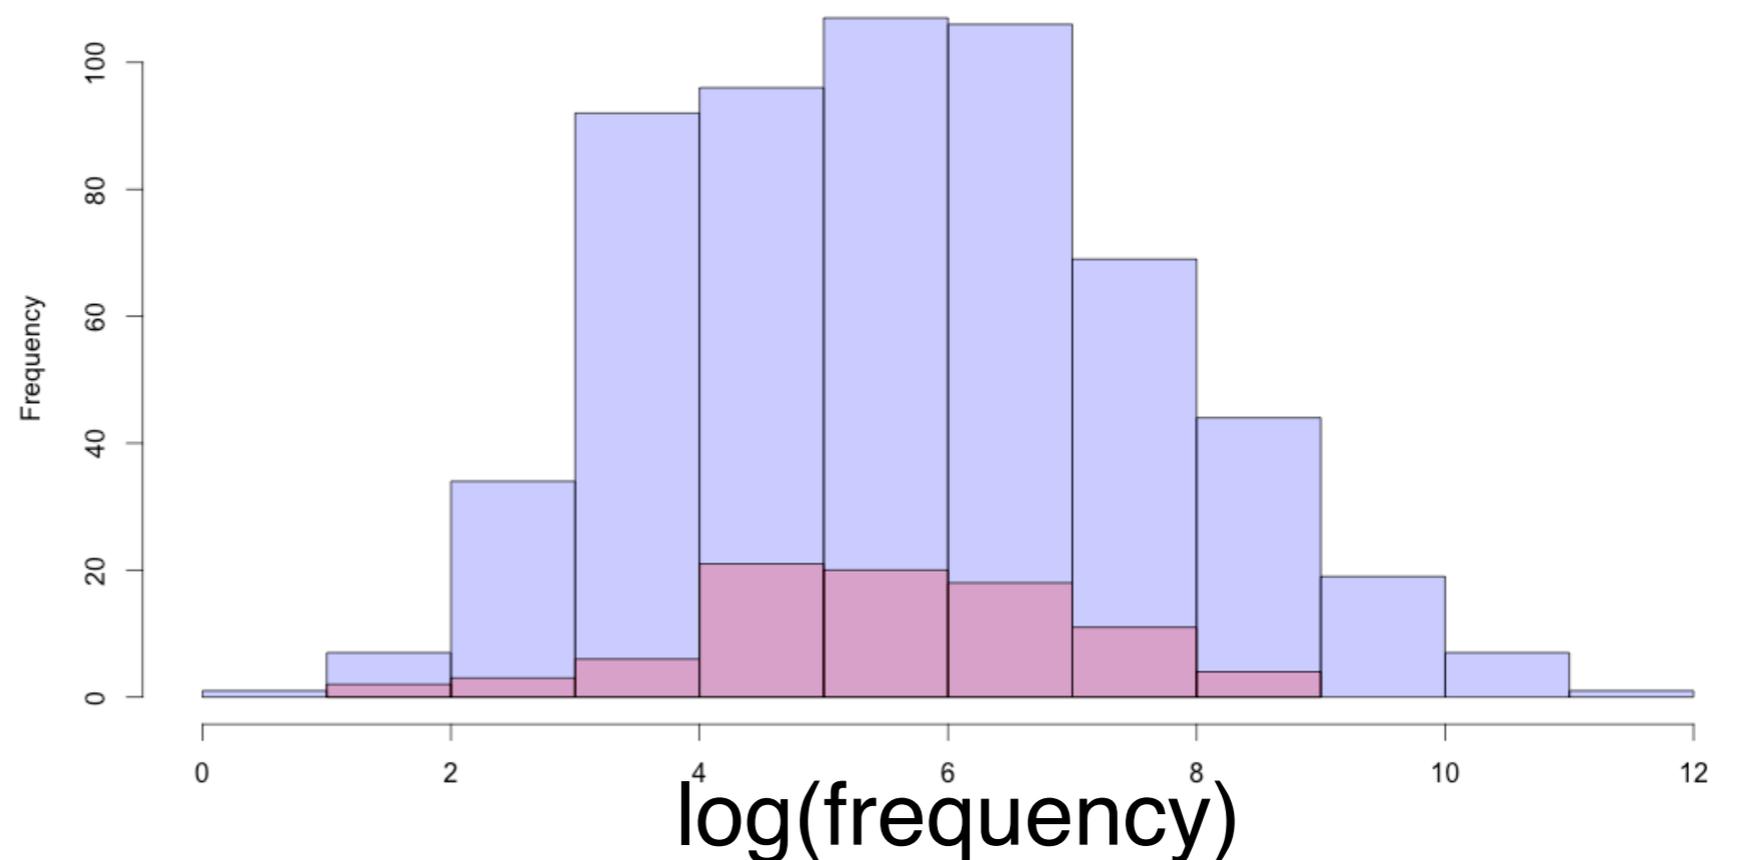

|                   | Predicted Diatonic | Predicted Isotonic |
|-------------------|--------------------|--------------------|
| Attested Diatonic | 62                 | 23                 |
| Attested Isotonic | 140                | 443                |

Fisher's exact test:  $p < 0.001$ , odds ratio = 8.50

# Lexical Frequency?

| Predictor              | Coef.  | S.E.  | <i>p</i>   |
|------------------------|--------|-------|------------|
| (Intercept)            | -3.470 | 0.688 | <0.001 *** |
| log(Freq)              | 0.089  | 0.111 | 0.422      |
| Halle (1998)           | 3.159  | 0.855 | <0.001 *** |
| log(Freq) x Halle 1998 | -0.179 | 0.141 | 0.204      |

Isotonic  
Diatonic

**\*(2, 1)**

- No N/V pair has ever surfaced as (2,1) but there are still plenty of 2 nouns (**today**) and 1 verbs (**follow**)
- If a word does not follow the structural description of a productive rule, then no amount of lexical similarity can trigger change
- This seems like a radical statement for proponents of analogy but the child language evidence for lexically based analogy is virtually non-existent (Berko 1958, Marcus et al. 1992, Xu & Pinker 1995, Clahsen et al. 2002, Yang 2002, Guasti 2004 ...)

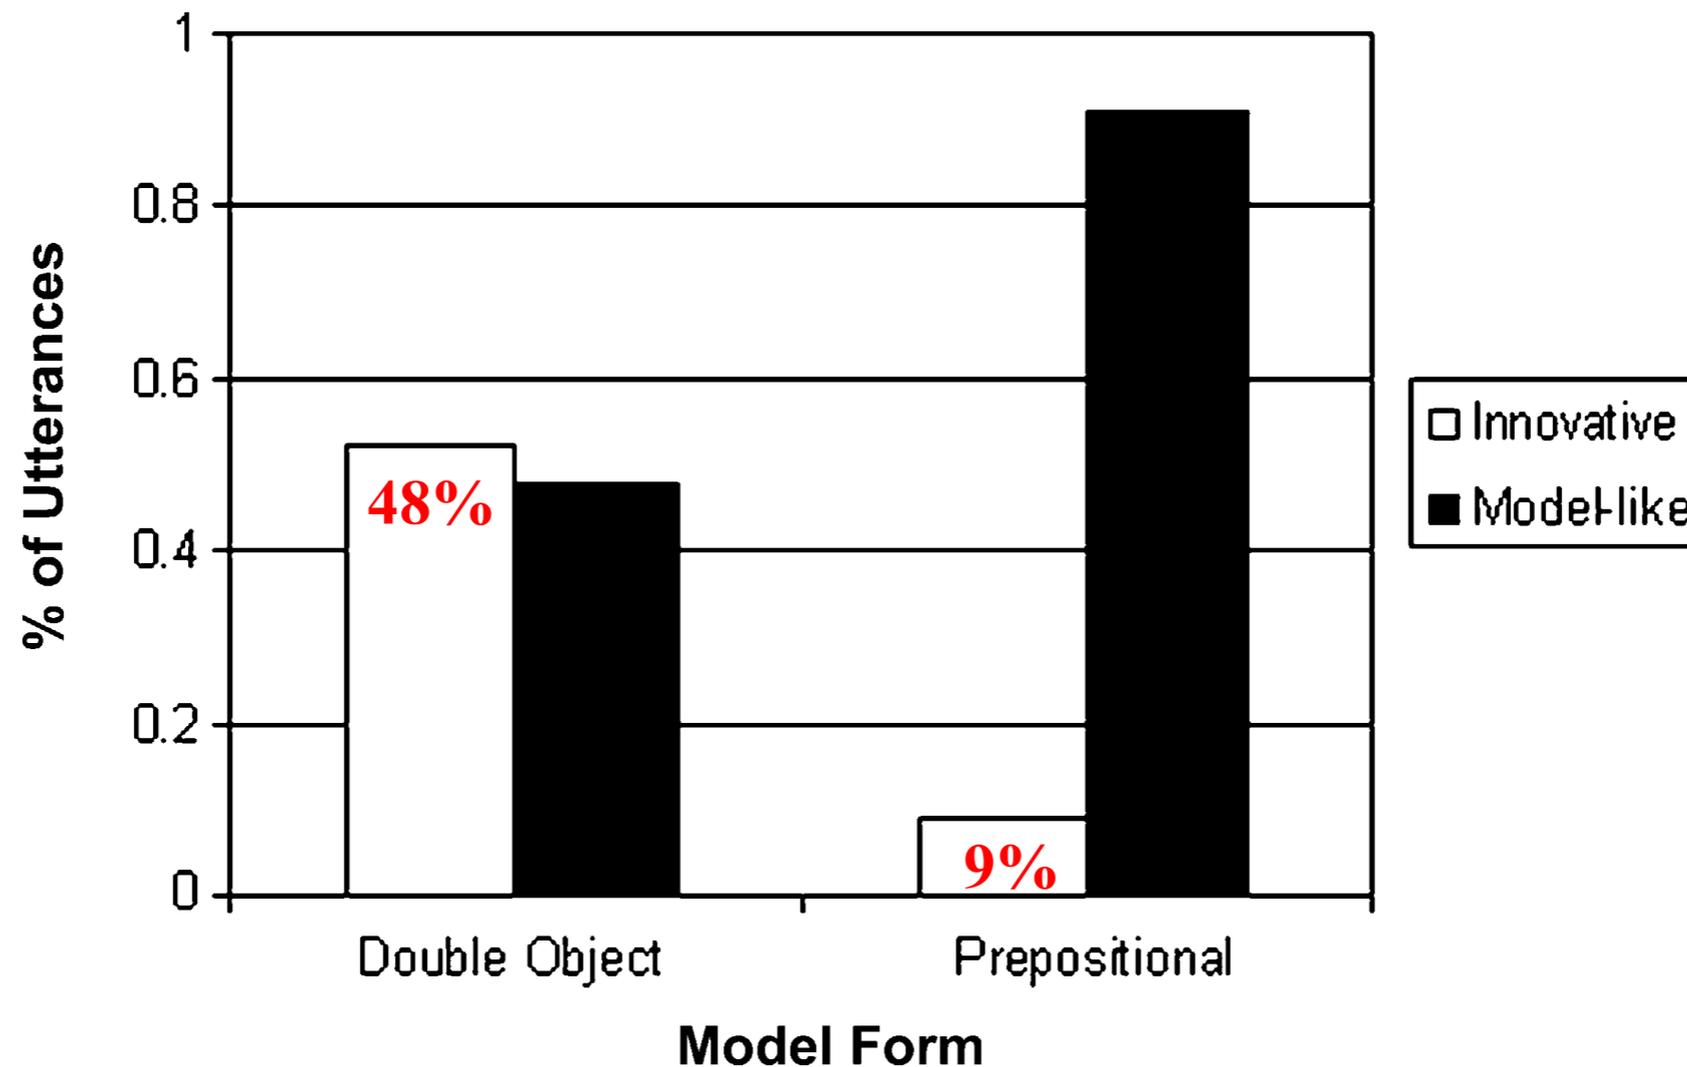

# Baker's Paradox

- a. John threw the ball to Bill.  
John threw Bill the ball.
- b. John told Bill the story.  
John told the story to Bill.
- c. John pushed the tea to Mary.  
\*John pushed Mary the tea.
- d. John donated the painting to the museum.  
\*John donated the museum the painting.

- How to generalize just enough? (I **texted** him my apology)

# Extension

- I pilked the cup to Petey  $\Rightarrow$  I picked Petey the cup
- I gorped Toby the key  $\Rightarrow$  I gorped the key to Toby

Conwell & Demuth (2007, *Cognition*)

# Dative Acquisition

- Pinker (1989): weakly conservative learning
- Broad Range Rules: semantic properties **necessary** for dative constructions
- Narrow Range Rules: subclasses with different productivity
  - “future giving”: offer, promise, bequeath, leave, refer, forward, allocate, guarantee, award, reserve ...
  - “continuous causation of accompanied motion”: pull, carry, push, schelp, lift, lower, haul ...
  - “telecommunication”: telegraph, fax, telephone, email, wire ...

# Datives cross linguistically

|                   | Greek | English | Warlpiri | Hebrew | Icelandic | Mandarin | Yaqui | Fongbe |
|-------------------|-------|---------|----------|--------|-----------|----------|-------|--------|
| <i>Give-type</i>  | Yes   | Yes     | Yes      | Yes    | Yes       | Yes      | Yes   | Yes    |
| Future having     | Yes   | Yes     | ND       | Yes    | Yes       | Yes      | ND    | ND     |
| <i>Send-type</i>  | Yes   | Yes     | Yes      | Yes    | Yes       | No       | No    | ND     |
| <i>Bring/take</i> | Yes   | Yes     | Yes      | Y/N    | Yes       | No       | ND    | ND     |
| <i>Throw-type</i> | Yes   | Yes     | Yes      | Yes    | No        | No       | No    | No     |
| <i>Push-type</i>  | No?   | No?     | No       | No?    | ND        | No       | ND    | ND     |

Datives must be acquired inductively on specific linguistic data

Children do not learn datives instantly (Snyder & Stromsworld 1995)

# Double Object and P Construction

- Two million words of child directed English
- Extracted all “dativizable” verbs from the list from Gropen et al. (1989) and Levin (1993)
- Manually documented whether a verb was used in Double Object and/or Prepositional Construction Construction at least once

# 50 DOC-able verbs

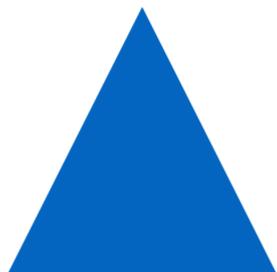

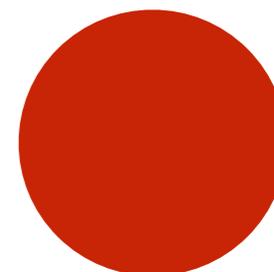

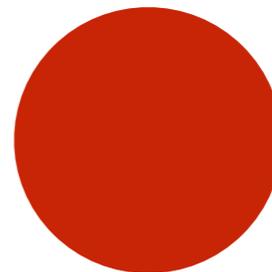

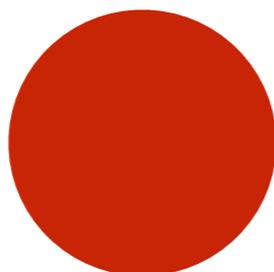

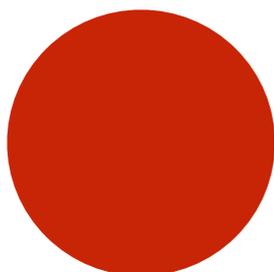

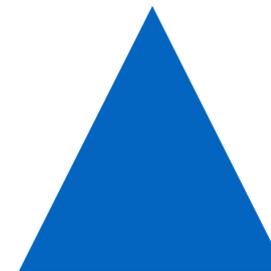

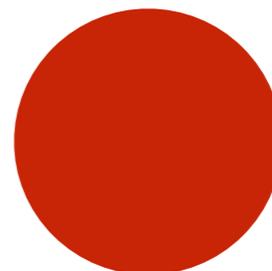

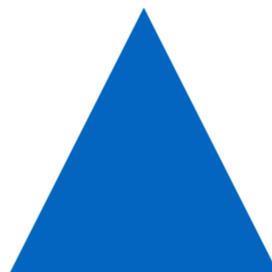

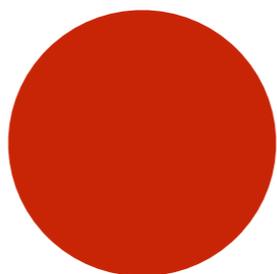

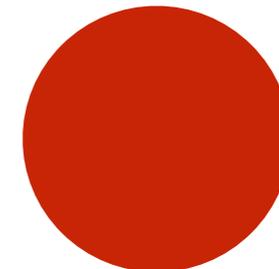

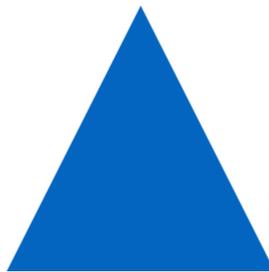

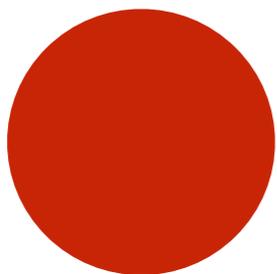

- give, pass, hand, sell, pay, trade, lend, loan, serve, feed
- throw, toss, flip, kick
- send, mail, ship
- bring, take
- offer, promise, leave, refer, forward, allocate, guarantee, award
- tell, show, ask, teach, write, read, quote
- bake, make, build, cook, sew, knit, toss, fix, pour
- get, buy, find, steal, order, win, earn, grab

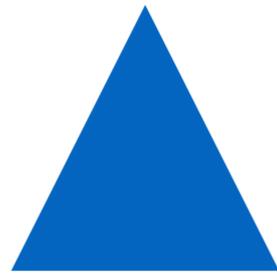

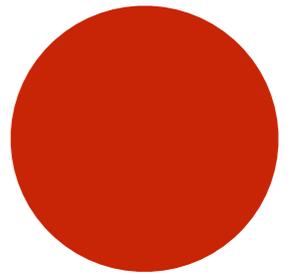

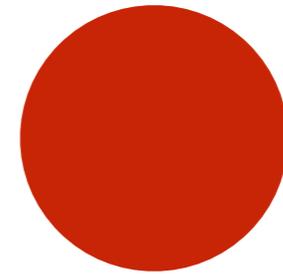

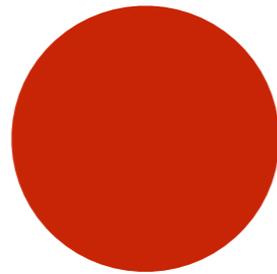

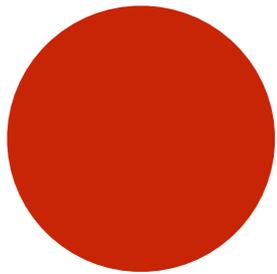

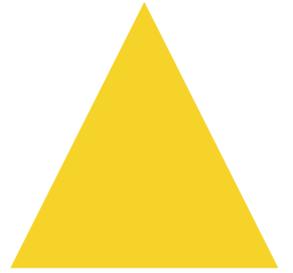

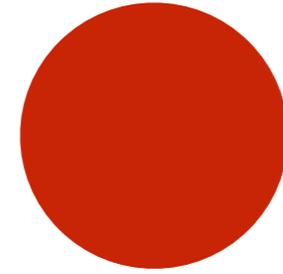

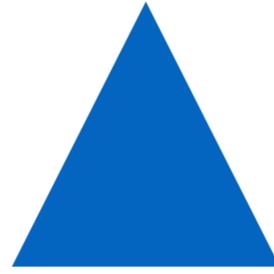

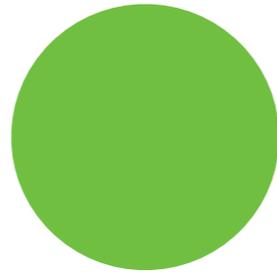

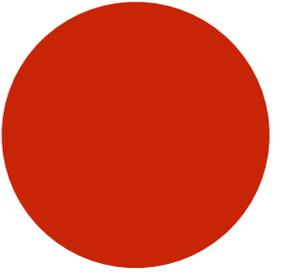

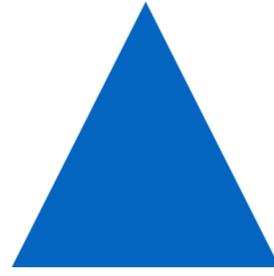

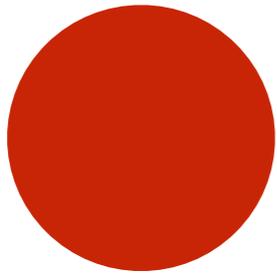

# Productivity of DOC

- N = 50 (e=13): 40 participate in DOC, **10** have not
  - DOC is a productive process in English
- DOC  $\Rightarrow$  PC: N=42, 40 participate in PC, **2** do not
  - Every DOC verb can be extended

# \*donate the museum the painting

- Latinate verbs generally don't participate in DOC: children show sensitivity to these morphological/phonological properties in novel verb extension tasks (Gropen et al. 1989)
- Only a tendency:
  - Latinate: **assign, advance, award, guarantee, reserve ...**
  - Germanic: **shout, trust, lift, pick, ...**
- Levin (1993): 70 Latinate verbs, only 10 participate in double object construction (cannot be studied with CDS)
  - Non-productivity is productive
  - **assign, advance, award, guarantee, reserve** are positive counterexamples that we lexicalize

# Approaching Actuation

- We now have reasonable descriptions, possibly even theories, of how children learn languages
- Linguistic data for acquisition is finite and subject to sampling effects
- Children will arrive at a range of productive hypotheses (e.g.,  $e < N / \ln N$ ), some of which will be ironed out, some will remain, including those that differ from the previous generation
- Examination of the statistical composition of historical data may give us clues of variants that got actuated
